<b>Re:</b>	<b>IEEE 802.16 Working Group Letter Ballot #24, on P802.16h/D1</b>	
<b>Abstract</b>	<b>This contribution proposes to enhance adaptive channel selection using 2-hop BS working channel ID to increase spatial efficiency.</b>	
<b>Purpose</b>	<b>To consolidate the working document</b>	
<b>Notice</b>	This document has been prepared to assist IEEE 802.16. It is offered as a basis for discussion and is not binding on the contributing individual(s) or organization(s). The material in this document is subject to change in form and content after further study. The contributor(s) reserve(s) the right to add, amend or withdraw material contained herein.	
<b>Release</b>	The contributor grants a free, irrevocable license to the IEEE to incorporate material contained in this contribution, and any modifications thereof, in the creation of an IEEE Standards publication; to copyright in the IEEE's name any IEEE Standards publication even though it may include portions of this contribution; and at the IEEE's sole discretion to permit others to reproduce in whole or in part the resulting IEEE Standards publication. The contributor also acknowledges and accepts that this contribution may be made public by IEEE 802.16.	
<b>Patent Policy and Procedures</b>	The contributor is familiar with the IEEE 802.16 Patent Policy and Procedures < <a href="http://ieee802.org/16/ipr/patents/policy.html">http://ieee802.org/16/ipr/patents/policy.html</a> >, including the statement "IEEE standards may include the known use of patent(s), including patent applications, provided the IEEE receives assurance from the patent holder or applicant with respect to patents essential for compliance with both mandatory and optional portions of the standard." Early disclosure to the Working Group of patent information that might be relevant to the standard is essential to reduce the possibility for delays in the development process and increase the likelihood that the draft publication will be approved for publication. Please notify the Chair < <a href="mailto:chair@wirelessman.org">mailto:chair@wirelessman.org</a> > as early as possible, in written or electronic form, if patented technology (or technology under patent application) might be incorporated into a draft standard being developed within the IEEE 802.16	

**Working Group. The Chair will disclose this notification via the IEEE 802.16 web site  
<<http://ieee802.org/16/ipr/patents/notices>>.**

**Introduction**

In November meeting, the part 1 of contribution S80216h-06\_101 (slide2 to slide 8) was accepted by the 16h task group. But the editorial change indication is not provided in S80216h-06\_101. Here we provide editorial change indication for the part 1 of the idea proposed in S80216h-06\_101.

The following is the summary of the part 1 of contribution S80216h-06\_101. One of the basic coexistence mechanisms of 802.16h is the adaptive channel selection. The IBS (initializing BS) finds a less interfering or less used frequency to work on. The algorithm in the current draft [1] randomly selects a non-interfering channel as IBS's working channel if there is at least one non-interfering channel. This may decrease frequency efficiency, as described in S80216h-06\_101 ([2]). We provide an enhancement to the algorithm in draft [1] to increase the frequency efficiency. The key idea is that an IBS selects one of its 2-hop OBS's (operating BS) working channels which are the IBS's non-interfering channels as its working channel. If the IBS cannot find any such a non-interfering channel, it randomly selects one of its non-interfering channels as the working channel.

**15.4.1.1 How to select a "free" channel (for ACS and DFS)**

*Update texts as follows (changes marked red):*

After Scanning before interference identification, the IBS should try to figure out whether it interferes with other systems in each of these candidate channels. **In the initialization phase of an IBS, its neighbors will send their current working channel ID, neighbor's working channel IDs, OCSI allocation and subframe allocation using CXP messages, as well as a flag having alternative channels. The IBS maintains the channel information of all 1-hop and 2-hop neighbors in the BS information table.**

If there is neither interference detected nor interference victims found in some channel by the IBS, the channel is marked as a "free" channel of the IBS. **When the IBS can find non-interfering channels at the initialization phase, it shall select its working channel as follows:**

**If the IBS can find non-interfering channels that are also its 2-hop neighbors' working channels, it randomly selects one from those non-interfering channels as its working channel.**

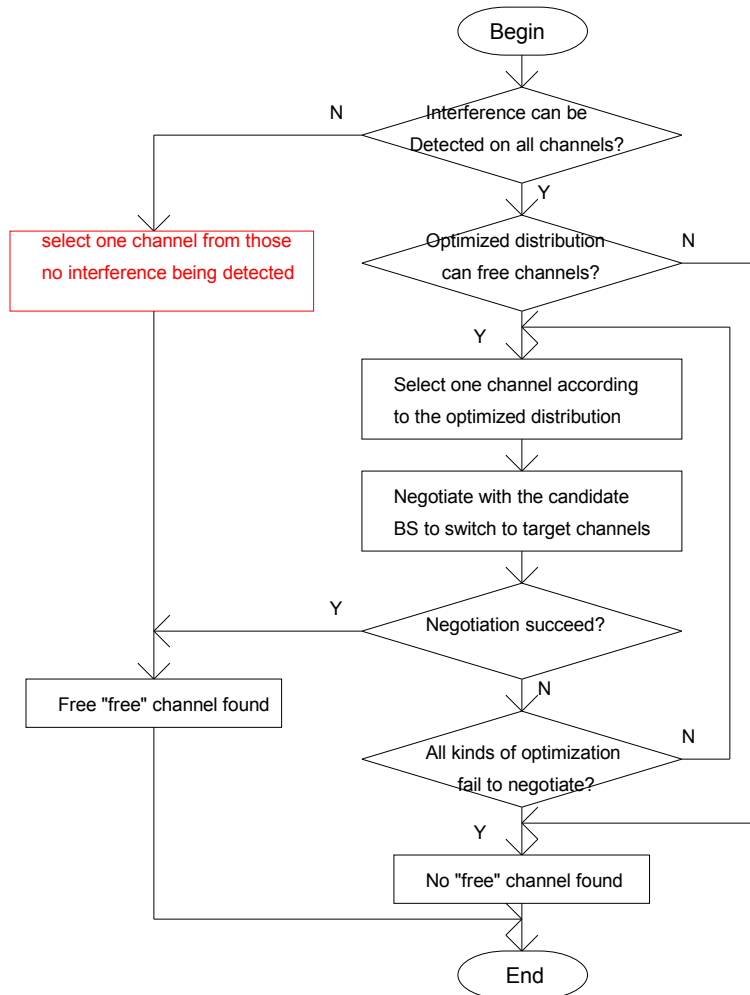

**Otherwise the IBS randomly selects one from all available non-interfering channels as its working channel.**

**When the IBS cannot find any non-interfering channel**, the IBS should figure out whether a "free" channel can be vacated by optimized channel distribution, as described in 15.4.1.2.

The process of ACS is shown in Figure h 38. The ACS process concludes with either one of two possible results: a) a "free" channel is validated with or without channel distribution optimization, or b) no "free" channel.

If a "free" channel is validated, it means default interference-free master slot is to be used; otherwise, the IBS needs to share the channel with coexistence neighbors, as described in 15.4.2.1.

Change Figure h38 as follows:

### 15.4.1.2 Optimization of Channel Distribution

Insert the following red text:

In the initialization phase of an IBS, its neighbors will send their current working channel ID, **neighbor's working channel IDs**, OCSI allocation and subframe allocation using CXP messages, as well as a flag having alternative channels. The IBS maintains the channel information of all **1-hop and 2-hop** neighbors in the BS information table.
