Base Document:
None
Purpose:
To recommend a correlated lognormal shadowing model for .16j network simulation

Notice:
This document has been prepared to assist IEEE 802.16. It is offered as a basis for discussion and is not binding on the contributing individual(s) or organization(s). The material in this document is subject to change in form and content after further study. The contributor(s) reserve(s) the right to add, amend or withdraw material contained herein.

Release:
The contributor grants a free, irrevocable license to the IEEE to incorporate material contained in this contribution, and any modifications thereof, in the creation of an IEEE Standards publication; to copyright in the IEEE’s name any IEEE Standards publication even though it may include portions of this contribution; and at the IEEE’s sole discretion to permit others to reproduce in whole or in part the resulting IEEE Standards publication. The contributor also acknowledges and accepts that this contribution may be made public by IEEE 802.16.

IEEE 802.16 Patent Policy:
The contributor is familiar with the IEEE 802.16 Patent Policy and Procedures <http://ieee802.org/16/ipr/patents/policy.html>, including the statement "IEEE standards may include the known use of patent(s), including patent applications, provided the IEEE receives assurance from the patent holder or applicant with respect to patents essential for compliance with both mandatory and optional portions of the standard." Early disclosure to the Working Group of patent information that might be relevant to the standard is essential to reduce the possibility for delays in the development process and increase the likelihood that the draft publication will be approved for publication. Please notify the Chair <mailto:chair@wirelessman.org> as early as possible, in written or electronic form, if patented technology (or technology under patent application) might be incorporated into a draft standard being developed within the IEEE 802.16 Working Group. The Chair will disclose this notification via the IEEE 802.16 web site <http://ieee802.org/16/ipr/patents/notices>.
Introduction

- In a network of base stations the lognormal shadowing from two different base sites at a given subscriber location will have some level of correlation. In order to correctly model the benefits of relaying this correlation needs to be modelled.
- In addition, the shadowing from a given base site at two different subscriber locations will be correlated if they are within the spatial decorrelation distance of the shadowing. Therefore relays need to be beyond the spatial decorrelation distance to have a beneficial effect for a subscriber, and the spatial correlation of the shadowing also needs to be modelled.
- The following slides present a relatively simple method for modelling real world shadowing correlation effects.
Lognormal Correlation

• C/I distribution in cellular networks is dependent on lognormal shadowing
  – Correlation between base stations
    • For a MS at a given location how similar is the signal from two different base stations?
  – Decorrelation distance between shadowing
    • For a given mobile, how far does it have to move for the shadowing to change?

• Realistic models are required to include these correlations
MOSAIC generates spatially correlated fading using a sum of $N$ products of cosines, whose periodicity is dependent on the $x$ and $y$ spatial coordinates. The $N$ wavenumbers ($k$) are random numbers, uniformly distributed within a range from 0 to $k_{max}$. The value of $k_{max}$ is dependent on the decorrelation distance required.

$$L(dB) = \sum_{n=1}^{N} \left( a \cdot \cos(k_{n-1} \cdot x + \phi_{n}) \cdot \cos(k_{n-2} \cdot y + \psi_{n}) \right)$$

Shadowing model for a single base

$$a = \sqrt{\frac{4 \cdot \sigma^2}{N}}$$

where $\sigma$ is the lognormal standard deviation in dB.

$\phi_{n}$ and $\psi_{n}$ are random phase terms uniformly distributed between 0 - $2\pi$. 
Correlation between Basestations

**Modified Saunders’s correlation model**

\[
p = \begin{cases} 
\sqrt{\frac{d_1}{d_2}} & \text{for } 0^\circ \leq \theta \leq \theta_T \text{ and } d_1 \geq \frac{d_c}{2} \\
\left(\frac{\theta_T}{\theta}\right)^y \sqrt{\frac{d_1}{d_2}} & \text{for } \theta_T \leq \theta \leq \pi \text{ and } d_1 \geq \frac{d_c}{2} \\
\sqrt{\frac{d_c}{2 \cdot d_2}} & \text{for } d_1 < \frac{d_c}{2} 
\end{cases}
\]

\[
\theta_T = 2 \cdot \sin^{-1}\left(\frac{d_c}{2 \cdot d_1}\right)
\]

\[d_c = 1/e \text{ decorrelation distance}\]

For a given network of basestations a correlation matrix \( R_{yy} \) can be calculated using the above model. If independent lognormal samples, \( x \), are generated using the model on the previous slide, these can then be correlated using \( R_{yy} \) to give correlated lognormal samples, \( y \).

\[
y(t) = T x(t)
\]

\[
R_{xy} = E[y(t) y(t)^H] = E[T x(t) [T x(t)]^H]
\]

\[
= T E[x(t) x(t)^H] T^H
\]

\[
= T T^H = T T^H
\]

\[
R_{yy} = U D U^H
\]

\[
D = D^{1/2} D^{1/2}
\]

\[
R_{yy} = (UD^{1/2}) (D^{1/2} U^H)
\]

\[
= (UD^{1/2}) (UD^{1/2})^H
\]

\[
= T T^H
\]
Lognormal Shadowing
CINR & spatial correlation

- 19 Node B’s
- 3 beams/sector
- $\sigma=10$ dB
- $d_c=280$ m

CINR using MOSAIC, including correlation between BS’s and spatial correlation.

CINR using ITU model, with no correlation between BS’s and no spatial correlation.

MOSAIC results in a physically representative coverage plot with clearly identifiable black spots.
Considerations for real world effects

• In practice, the spatial decorrelation distance is not equal in all directions
  – Mobiles moving along a radial line from the basestation have longer decorrelation distances than mobiles moving along a circumferential path
  – More realism can be added by defining wavenumbers in polar coordinates \((r,\phi)\) instead of Cartesian coordinates \((x,y)\)
  – The shadowing is highly likely to be lowest (left tail of the Gaussian distribution) when the mobile is moving along a radial direction from the base station (street aligned with the basestation), as in many cases it will have a good LOS back to the base site. This needs to be accounted for in the model. The standard deviation will also be reduced in this case.
  – The lognormal standard deviation will have some dependence on the subscriber range, and will tend to decrease as range decreases. Some account of this is required in the model to prevent very large values of the standard deviation occurring at very short ranges in the network simulation.
Modified MOSAIC

\[
L(dB) = \begin{cases} 
-1.5\sigma \cos(|\phi - \phi_s|) + \sqrt{\frac{2\sigma}{3N}} \sum_{n=1}^{N} \cos(k_n^r r + \psi_n^r) & \text{for } |\phi - \phi_s| < 5^\circ \\
\sqrt{\frac{4\sigma^2}{N}} \sum_{n=1}^{N} \cos(k_n^r r + \psi_n^r) \cos(k_n^\phi \phi + \psi_n^\phi) & \text{for } |\phi - \phi_s| \geq 5^\circ 
\end{cases}
\]

where,
\[\sigma = \text{standard deviation of the lognormal shadowing}\]
\[\phi = \text{mobile bearing from the basestation}\]
\[\phi_s = \text{Street orientation at mobile location}\]
\[r = \text{range of mobile from basestation}\]
\[k_n^r = n^{th} \text{ wavenumber in the radial direction}\]
\[k_n^\phi = n^{th} \text{ wavenumber in the } \phi \text{ direction}\]
\[\psi_n^r, \psi_n^\phi = \text{Random phase terms}\]

\(\sigma\) is reduced by one third in this (radial, LOS) case.
The plot shows the variation of the shadowing for a mobile moving along a street aligned with the mobile bearing, and for a mobile moving along a street whose orientation is at 30° to the mobile bearing.

For the case where the street is aligned with the mobile bearing the shadowing is clearly in the lower portion of the shadowing distribution, and it has a much reduced standard deviation.

The plot also shows the distance dependant lognormal $\sigma$.

The maximum values of the wavenumbers can be adjusted to give the desired decorrelation distance. The precise values used in the equation for $\sigma$ can also be adjusted as desired.

$$\max(k'_{n}) = \frac{2\pi}{100} \quad \max(k_{n}^\phi) = 20\pi$$

$$\sigma = 10 \left(1 - e^{-\frac{3r}{200}}\right)$$
The model is constructed so that the shadowing is low (signal level high) when the street is aligned with the mobile bearing ($\phi = 0^\circ$ for the above case). At $5^\circ$ there is a sharp discontinuity as the mobile moves out of the aligned street. This is consistent with effects observed in real environments.
Example measurement in Central London

Measurements have been filtered using a moving average window to remove small scale fading. The plot shows the large scale fading. Each ‘average’ power delay profile in the plot is normalised to its own maximum, so that the plot shows the variation in profile shape with distance. The absolute power variation is shown below:

Mobile crossing a street junction. Note the increase in absolute received power.
Summary

- A model has been presented which allows the lognormal shadowing between basestations in a network to be correlated, for the BS-RS or BS-MS links.
- The model includes a simple model for including spatial correlation of the shadowing, which has an \((r,\phi)\) dependence, and which ensures that the shadowing is low when the street orientation is aligned with the mobile bearing.
- A distance dependant lognormal \(\sigma\) is proposed to ensure that large shadowing variations do not occur at very short ranges.
- Recommend to adopt the model for network simulation of .16j relaying system
