Re:	Submitted in response to Call for Technical Proposals for IEEE 802.16j issued on 2006-10-15
Abstract	This contribution describes a cooperative ARQ scheme for relay stations as being defined in the IEEE 802.16j. It aims to improve the network performance through space time diversity. This is done by allowing retransmission of a failed packet being performed by an overhearing node, instead of the original transmitter node.
Purpose	The cooperative ARQ scheme is to be considered for Section 6.3.4.6 ARQ Operation.
Notice	This document has been prepared to assist IEEE 802.16. It is offered as a basis for discussion and is not binding on the contributing individual(s) or organization(s). The material in this document is subject to change in form and content after further study. The contributor(s) reserve(s) the right to add, amend or withdraw material contained herein.
Release	The contributor grants a free, irrevocable license to the IEEE to incorporate material contained in this contribution, and any modifications thereof, in the creation of an IEEE Standards publication; to copyright in the IEEE's name any IEEE Standards publication even though it may include portions of this contribution; and at the IEEE's sole discretion to permit others to reproduce in whole or in part the resulting IEEE Standards publication. The contributor also acknowledges and accepts that this contribution may be made public by IEEE 802.16.
Patent Policy and Procedures	The contributor is familiar with the IEEE 802.16 Patent Policy and Procedures < http://ieee802.org/16/ipr/patents/policy.html >, including the statement "IEEE standards may include the known use of patent(s), including patent applications, provided the IEEE receives assurance from the patent holder or applicant with respect to patents essential for compliance with both mandatory and optional portions of the standard." Early disclosure to the Working Group of patent information that might be relevant to the standard is essential to reduce the possibility for delays in the development process and increase the likelihood that the draft publication will be approved for publication. Please notify the Chair < mailto:chair@wirelessman.org > as early as possible, in written or electronic form, if patented technology (or technology under patent application) might be incorporated into a draft standard being developed within the IEEE 802.16 Working Group. The Chair will disclose this notification via the IEEE 802.16 web site < http://ieee802.org/16/ipr/patents/notices >.

An ARQ scheme for IEEE 802.16j multihop relay networks

IEEE 802.16j is the IEEE standardization Task Group defining Mobile Multihop Relay (MMR) Specification for Broadband Wireless Access Systems. MMR is a promising solution to expand coverage and to enhance throughput and system capacity for IEEE 802.16 systems. It is expected that the complexity of relay stations (RS) will be considerably less than the complexity of legacy IEEE 802.16 base stations (BS). The gains in coverage and throughput can be leveraged to reduce total deployment cost for a given system performance requirement and thereby improve the economic viability of IEEE 802.16 systems. Also, relay functionality enables rapid deployment and reduces the cost of system operation. These advantages will expand the market opportunity for broadband wireless access.

Fig. 1 shows a typical usage scenario for MMR where a subscriber station (SS) is connected to the BS via one or multiple RS [1]. In this context, downlink transmission is from BS to SS and uplink transmission is from SS to BS. Thus, a RS will transmit for both downlink and uplink traffic compared to BS that can only transmit downlink traffic and SS that can only transmit uplink traffic.

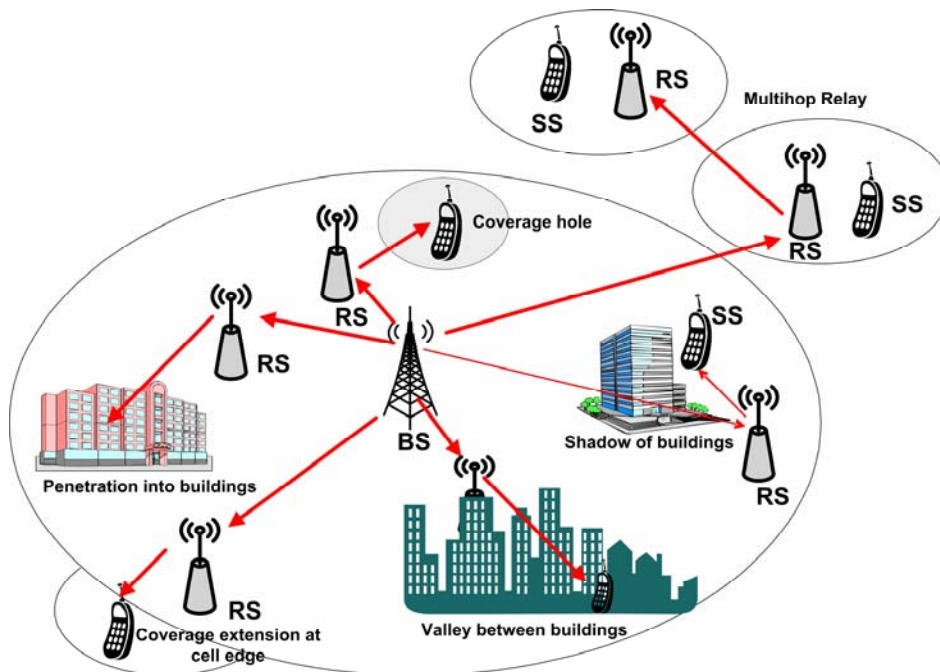

Fig. 1. A typical usage scenario of MMR

In downlink, as illustrated in Fig. 2, a transmission from BS to SS1 happens in two hops via RS1. In the first hop, transmissions from BS could be overheard by RS2 and RS3. Traditionally, when the transmission fails, BS is required to retransmit the failed packet. This may not be effective if the link between BS and RS1 is broken for an extended duration resulting in failures for all subsequent retransmissions. Since RS2 and RS3 have overheard the original transmission, they could effectively retransmit the failed packet on behalf of BS, and thus provide space time diversity. This retransmission from an overhearing RS could be sent directly to the SS1 if the overhearing RS is within the range of SS1. An example of this is given by RS2 in Fig. 2. If the overhearing RS is within the range of RS1 but not SS1 as illustrated by RS3 in Fig. 2, the retransmission will be sent to RS1. We call this cooperative retransmission because the overhearing RS and the original transmitter node are cooperating among themselves for a successful transmission. For simplicity, we call the overhearing RS or BS that helps in the retransmission the cooperative node. To realize the cooperative retransmission, we propose here a cooperative ARQ scheme. One requirement in IEEE 802.16j specification is that there will be no change to IEEE 802.16e SS [2]. Thus, our proposal introduces only changes to BS and RS but not SS, and operates on the link between non-SS nodes.

Fig. 2. An example of two-hop transmission between BS and a SS

When both the original transmitter node and the intended receiver node are not SS as illustrated in Fig. 3, C-NACK will be sent out by the intended receiver node when an erroneous packet is detected and there is an identified cooperative node. The C-NACK contains information indicating the identified cooperative node that should retransmit the failed packet and to which node the retransmission should be sent to. The cooperative node and receiver node are determined using Algorithm 1.

```

//Decision on performing actual or pseudo retransmission by the original transmitter node.
//Link quality is calculated as the ratio of total number of packets positively acknowledged
//over total number of packets transmitted. If the ratio is not more than 0.5, the link quality
//is consider bad.
if (link quality between original transmitter and intended receiver is bad)
    mode = 2;
else
    mode = 1;

//Decision on selecting cooperative node and receiver node.
//S1 is the set of nodes with good link quality, and are within the range of the original
//transmitter node, the intended receiver node and the downstream node of intended
//receiver.
//S2 is the set of nodes with good link quality, and are within the range of the original
//transmitter node and the intended receiver node.
// Q1,i is the link quality between i-th node in S1 and the downstream node of intended
//receiver.
// Q2,i is the link quality between i-th node in S2 and the intended receiver node.
// Wk,i is the willingness to cooperate as declared by the i-th node in Sk.
if (S1 is not empty) {
    cooperative node = arg maxi ∈ S1 {W1,i × Q1,i};
    receiver node = downstream node of the intended receiver;
}
else if (S2 is not empty) {
    cooperative node = arg maxi ∈ S2 {W2,i × Q2,i};
    receiver node = intended receiver;
}
else
    original ARQ procedure;

```

Algorithm 1. Decision algorithm for cooperative retransmission

The C-NACK is sent out using a C-ARQ IE with a format given in Table 1. Upon receiving the C-NACK, the cooperative node schedules to transmit once the overheard packet using the following scheduling algorithm.

```

generate a random number  $x$  within the range and inclusive of 0 and 1
if ( $x \leq P_1$  and own packet queue is not empty)
    transmit own packet;
else if ( $x \leq P_1 + P_2$  and retransmission queue is not empty)
    retransmit own failed packet;
else if ( $x \leq P_1 + P_2 + P_3$  and identified as cooperative node and the failed packet is buffered)
    retransmit overheard failed packet;

//  $P_1 + P_2 + P_3 = 1$ 
//  $P_1 \geq P_2 + P_3$ .
// Suggestion:  $P_1 = 2 \times (P_2 + P_3)$  and  $P_2 = P_3$ 
    
```

Algorithm 2. Scheduling algorithm for cooperative retransmission

On the other hand, the original transmitter node will enter the “waiting for retransmission” state as illustrated in Fig. 4 which is a modification from Figure 33 in the current IEEE Standard 802.16 specification document [3]. In this state, the scheduling for retransmission is performed using Algorithm 1. To transition from this state, there are two modes of operation, namely mode 1 and mode 2. In mode 1, the original process is followed. In mode 2, the original transmitter node will transition to the “outstanding” state following the normal process which includes starting the ARQ_RETRY_TIMEOUT timer but not actually transmitting the packet. This process of pretending retransmission at the original transmitter node is labeled as “Pseudo Retransmit” in Fig. 4.

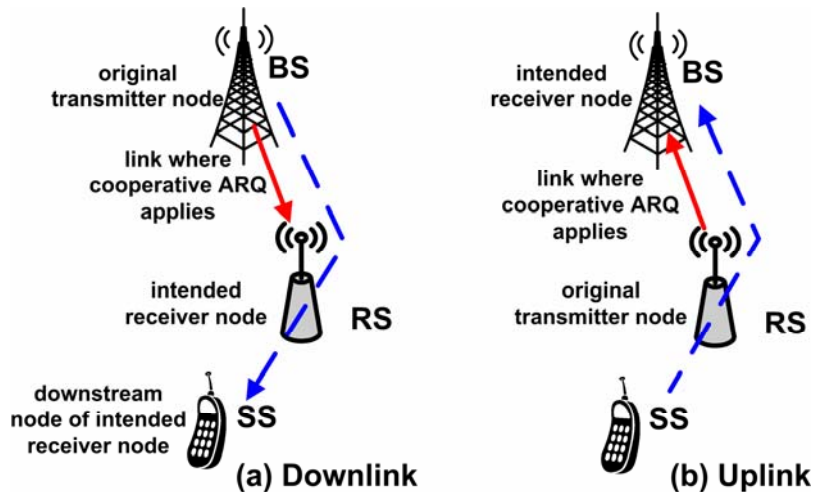

Fig. 3. Links where cooperative ARQ is applied

If ARQ_RETRY_TIMEOUT timer expires without any negative acknowledgment received as illustrated in Fig. 5, the original transmitter node may decide to retransmit the failed packet or delegate the retransmission to a cooperative node. In both cases, as illustrated in Fig. 4, the node will enter “waiting for retransmission” state eventually. If the retransmission is delegated, the node will immediately send out a C-ARQ Command using the C-ARQ IE before entering the “waiting for retransmission” state. The C-ARQ Command indicate the cooperative node that should retransmit the failed packet and to which node. Upon

receiving the C-ARQ Command, the cooperative node schedules to transmit once the overheard packet using Algorithm 1.

Proposed Text:

BEGIN PROPOSED TEXT

[Add to new Section 6.3.4.6.4]

When a block transmission involves at least one non-SS hop that has non-SS nodes at both its end points, the ARQ transmit block sequence in Figure XX1 instead of Figure 33 should be used.

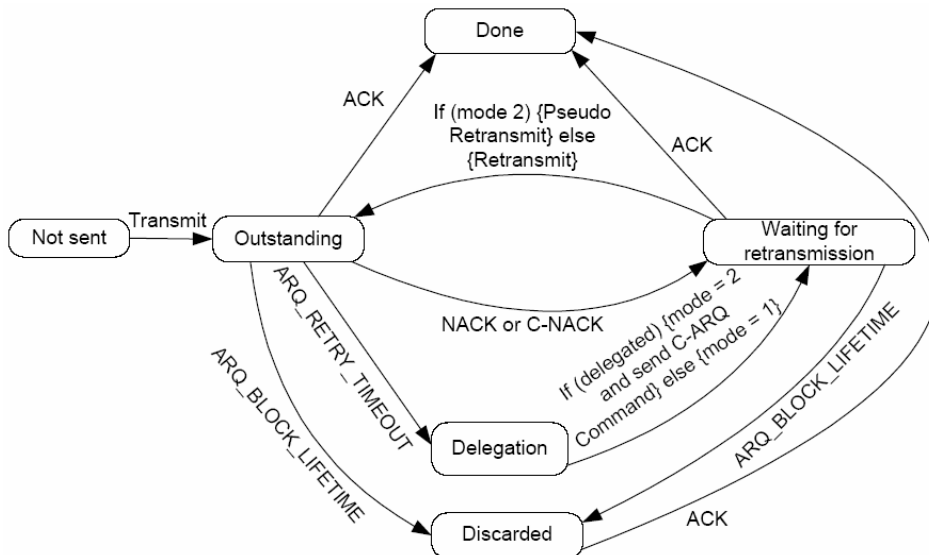

Figure XX1. C-ARQ transmit block states

An ARQ block may be in one of the following five states — not-sent, outstanding, discarded, delegation, and waiting-for-retransmission. Any ARQ block begins as not-sent. After it is sent it becomes outstanding for a period of time termed ACK_RETRY_TIMEOUT. While a block is in outstanding state, it is either acknowledged with ACK and discarded, or transitions to waiting-for-retransmission after ACK_RETRY_TIMEOUT, or upon receiving a negative acknowledgement. If an ACK_RETRY_TIMEOUT occurs, the ARQ block first transitions to delegation state before ultimately

entering waiting-for-retransmission state. In the delegation state, the original transmitter node may decide to retransmit the failed packet itself (operation mode 1) or delegate the retransmission (operation mode 2) to a cooperative node. In both cases (mode 1 and mode 2), the node will enter waiting for retransmission state eventually. If the retransmission is delegated (operation is in mode 2), the node will immediately send out a C-ARQ Command using the C-ARQ IE with a format given in Table XX1 before entering the waiting-for-retransmission state. The C-ARQ Command indicate the cooperative node that should retransmit the failed packet and to which node. The cooperative node and the receiver node are determined using Algorithm XX1. Upon receiving the C-ARQ Command, the cooperative node schedules to transmit once the overheard packet using Algorithm XX2. In mode 1, the normal ARQ process is followed after entering waiting-for-retransmission state. In mode 2, the original transmitter node will transition from waiting-for-retransmission state to the outstanding state following the normal process which includes starting the ARQ_RETRY_TIMEOUT timer but not actually transmitting the packet. This process of pretending retransmission at the original transmitter node is labeled as “Pseudo Retransmit” in Figure XX1.

```

//Decision on performing actual or pseudo retransmission by the original transmitter node.
//Link quality is calculated as the ratio of total number of packets positively acknowledged
//over total number of packets transmitted. If the ratio is not more than 0.5, the link quality
//is consider bad.
if (link quality between original transmitter and intended receiver is bad)
    mode = 2;
else
    mode = 1;

//Decision on selecting cooperative node and receiver node.
//S1 is the set of nodes with good link quality, and are within the range of the original
//transmitter node, the intended receiver node and the downstream node of intended
//receiver.
//S2 is the set of nodes with good link quality, and are within the range of the original
//transmitter node and the intended receiver node.
// Q1,i is the link quality between i-th node in S1 and the downstream node of intended
//receiver.
// Q2,i is the link quality between i-th node in S2 and the intended receiver node.
// Wk,i is the willingness to cooperate as declared by the i-th node in Sk.
if (S1 is not empty) {
    cooperative node = arg maxi ∈ S1 {W1,i × Q1,i};
    receiver node = downstream node of the intended receiver;
}
else if (S2 is not empty) {
    cooperative node = arg maxi ∈ S2 {W2,i × Q2,i};
    receiver node = intended receiver;
}
else
    original ARQ procedure;

```

Algorithm XX1. Decision algorithm for cooperative retransmission

An ARQ block can become waiting-for-retransmission before the ACK_RETRY_TIMEOUT period expires if it is negatively acknowledged using NACK or C-NACK. C-NACK will be sent out by an intended

receiver node when an erroneous packet is detected and there is an identified cooperative node. The C-NACK contains information indicating the identified cooperative node that should retransmit the failed packet and to which node the retransmission should be sent to. The cooperative node and receiver node are determined using Algorithm XX1. The C-NACK is sent out using a C-ARQ IE with a format given in Table XX1. Upon receiving the C-NACK, the cooperative node schedules to transmit once the overheard packet using the Algorithm XX2.

```

generate a random number  $x$  within the range and inclusive of 0 and 1
if ( $x \leq P_1$  and own packet queue is not empty)
    transmit own packet;
else if ( $x \leq P_1 + P_2$  and retransmission queue is not empty)
    retransmit own failed packet;
else if ( $x \leq P_1 + P_2 + P_3$  and identified as cooperative node and the failed packet is buffered)
    retransmit overheard failed packet;

//  $P_1 + P_2 + P_3 = 1$ 
//  $P_1 \geq P_2 + P_3$ .
// Suggestion:  $P_1 = 2 \times (P_2 + P_3)$  and  $P_2 = P_3$ 

```

Algorithm XX2. Scheduling algorithm for cooperative retransmission

An ARQ block may also change from wait-for-retransmission or outstanding to discarded after a timeout of ARQ_BLOCK_LIFETIME.

Syntax	Size	Notes
C-ARQ_IE(LAST) {	<i>variable</i>	
COOPERATIVE NODE	16 bits	The identified Cooperative Node
LAST	1 bit	0 = More C-ARQ IE in the list 1 = Last C-ARQ IE in the list
TYPE	2 bits	0x0 = C-ARQ Feedback (C-NACK) 0x1 = C-ARQ Command 0x2 = reserved 0x3 = reserved
CID	16 bits	The ID of the connection being referenced
BSN	11 bits	Block Sequence Number
MODE	2 bits	0x0 = reserved 0x1 = Not Pseudo Retransmission 0x2 = Pseudo Retransmission 0x3 = reserved
RECEIVER NODE	16 bits	The identified Receiver node
}
