Re:	A response to a Call for Technical Proposal, http://wirelessman.org/relay/docs/80216j-06_027.pdf
Abstract	This contribution proposes a procedure regarding how to reuse 802.16e preamble resource among MMR-BS and RSs
Purpose	To incorporate the proposed text into the P802.16j Baseline Document (IEEE 802.16j-06/026)
Notice	This document has been prepared to assist IEEE 802.16. It is offered as a basis for discussion and is not binding on the contributing individual(s) or organization(s). The material in this document is subject to change in form and content after further study. The contributor(s) reserve(s) the right to add, amend or withdraw material contained herein.
Release	The contributor grants a free, irrevocable license to the IEEE to incorporate material contained in this contribution, and any modifications thereof, in the creation of an IEEE Standards publication; to copyright in the IEEE's name any IEEE Standards publication even though it may include portions of this contribution; and at the IEEE's sole discretion to permit others to reproduce in whole or in part the resulting IEEE Standards publication. The contributor also acknowledges and accepts that this contribution may be made public by IEEE 802.16.
Patent Policy and Procedures	The contributor is familiar with the IEEE 802.16 Patent Policy and Procedures <http://ieee802.org/16/ipr/patents/policy.html>, including the statement "IEEE standards may include the known use of patent(s), including patent applications, provided the IEEE receives assurance from the patent holder or applicant with respect to patents essential for compliance with both mandatory and optional portions of the standard." Early disclosure to the Working Group of patent information that might be relevant to the standard is essential to reduce the possibility for delays in the development process and increase the likelihood that the draft publication will be approved for publication. Please notify the Chair <mailto:chair@wirelessman.org> as early as possible, in written or electronic form, if patented technology (or technology under patent application) might be incorporated into a draft standard being developed within the IEEE 802.16 Working Group. The Chair will disclose this notification via the IEEE 802.16 web site <http://ieee802.org/16/ipr/patents/notices>.

RS 802.16e Preamble Transmission

Nortel

Introduction

A RS may need to transmit the 802.16e preamble to facilitate a MS to perform cell selection and etc. Based on the 802.16e-2005 standard, there are total 114 preamble sequences (identified by preamble and characterized by IDcell, segment and PN sequence) for 1024 FFT and 512 FFT modes. This preamble resource pool now needs to be shared by not only MMR-BSs, but also RSs which are configured to transmit the 802.16e preamble. This contribution proposes a procedure regarding how to reuse 802.16e preamble resource among MMR-BS and RSs.

RS 802.16e preamble selection

During RS initial network entry, a RS needs to perform the cell selection as a MS does. This procedure can be enhanced to enable the RS assistant preamble PN sequence selection. The procedure includes the following steps:
- A RS maintains a table with each entry contains preamble index, corresponding PN sequence and strength
- A RS shall measure each preamble listed in the table
- The strength of each preamble is recorded in the table for the corresponding entry
- This measurement may take relative long time to minimize the impact of fading
- When the measurement procedure is finished (e.g., reach the required number of frames and so on), the RS may use certain criteria to determine its serving station (MMRBS or a RS)
- There are tow options regarding how to select a preamble for a RS
    i. The RS uses the same table to determine the candidate preamble pool for purpose of a preamble selection for its own transmission after it assumes RS function
    ii. The candidate preambles in the candidate pool are those preambles whose strengths measured by this RS are lower than a pre-defined threshold
    iii. The RS then randomly selects N preambles from the candidate pool and reports to its MMRBS (may via other RS(s)). The selected preambles are indicated by preamble index
    iv. The MMRBS may assign a preamble based on information from the list reported by this RS and information such as preamble currently used within the cell and by its neighbor cell (assume this information can be shared by neighbor MMRBS through backhaul) and signal the determination to the RS

The benefits of this approach include
- By reasonable setting of threshold and measure time, the preamble collision can be minimized
- Complex preamble plan can be fully avoided

Simulation Setup

The performance of the proposed method for RS-preamble selection is evaluated using the parameters from [1]. The following sections describe the simulation setup and assumptions for the performance evaluation of RS preamble selection.

BS deployment:
We consider a multi-cell layout assuming a 2-tier cell coverage model with 19 hexagonal cells (including the central BS cell). The relay deployment is performed within the 2-tier cell area. To cover the effect of base stations on the first and second tiers (with respect to the central cell), we also model the third and fourth tiers; however, we neglect the relay deployment in these two outer tiers.

Figure 1 Hexagonal grid for BS deployment

Each cell is separated into 3 sectors and each BS is equipped with a 3-sector antenna. Each sector is assigned a cell_ID and a segment_ID which together determine the PN sequence (preamble index) to be employed for preamble transmission. By convention, we assume that sectors within the same cell have the same cell_ID. A preamble index can be reused by a BS only if that index is not being used by any other BS within the 2-tier cell coverage area.

RS deployment:
In our simulation for fixed relays, RSs are created randomly within the 2-tier cell area with the following constraints

- The distance between any BS and any RS can not be smaller than a specified value
- The distance between any two RSs can not be smaller than a specified value

Any relay, whenever created, starts monitoring the preamble transmissions (which happens at the first OFDM symbol of every DL subframe period) from 19 BSs and any RSs if there exists any in the coverage area. After a sufficient observation period, it determines a set of PN sequences for which the correlation metric (whose computation is described below) is less than some threshold and the PN index for which the correlation metric is the maximum one. We initially assume that the PN sequence with the maximum correlation metric belongs to the serving station and those PN sequences that have a segment_ID different from the segment_ID of the serving station are considered for potential PN sequences to be assigned to the RSs.

Signal Model

The preamble symbols are generated and modulated according to the IEEE 802.16e-2005 standard. Basically, a preamble symbol consists of a number of left and right guard tones and a PN sequence, all specified by the standard. Let $\mathbf{p}_l = [p_l[0], p_l[1], \dots, p_l[K-1]]^T$ denote the transmitted symbols at tone-k, $k=0,..,K-1$, of the preamble symbol, where $l = 0, \dots, 113$, is the index of the PN sequence, and K is the FFT size (that can be 128, 512, 1024 or 2048). The signal received by a RS at tone-k can be expressed as (assuming synchronized transmissions from all nodes)

$$r[k] = \sum_m p_m[k] h_m[k] + z[k]$$

where the summation over m refers to the superposition of signals from all surrounding base or relay stations and $h[k]$ and $z[k]$ denotes the channel gain and additive Gaussian noise, respectively, at tone-k. The channel gains (that govern the effect of path loss, shadowing and small scale fading) are simulated using the methods and parameters in [1] and references therein. Let $\mathbf{r} = [r[0], r[1], \dots, r[K-1]]^T$ denote the received signal in vector form. Once a relay receives the preamble symbol, it computes the cross correlation between the received signal and each PN sequence:

$$\rho_l = \frac{|\langle \mathbf{p}_l, \mathbf{r} \rangle|}{\|\mathbf{p}_l\| \|\mathbf{r}\|}, \; l = 0, \dots, 113.$$

This is repeated over a number of frames, say F frames, and the resulting cross correlation is averaged by a moving average window

$$\bar{\rho}_l[f] = \begin{cases} \rho_l[0] & f = 0 \\ (1-\alpha)\bar{\rho}_l[f-1] + \alpha\rho_l[f] & f = 1, \dots, F-1 \end{cases}. \tag{1}$$

For fixed RSs, we set $\alpha = \dfrac{1}{f+1}$ so that the resulting correlation is the mean of the cross-correlation values across F frames. For a moving RS, it is possible to adjust this parameter appropriately to account for the variations of the RSs and BSs that cover the RS.

Evaluation of Interference:
To assess the effect of interference on the preamble selection, we define two interference metrics
- Interference based on average cross correlations

$$\Gamma_l = \frac{\bar{\rho}_l}{\sum_{m \neq l} \bar{\rho}_l} \tag{2}$$

- Interference based on received signal power

3

$$\gamma_l = \frac{\left\| \mathbf{p}_l . \mathbf{h}_l \right\|}{\left\| \mathbf{r} - \mathbf{p}_l . \mathbf{h}_l \right\|} .$$

(3)

Note that the product in (3) is point-wise product, e.g., $\mathbf{p}_l . \mathbf{h}_l = \left[p_l[0]h_l[0], \ldots, p_l[K-1]h_l[K-1] \right]^T$.

Performance Criteria and Simulation Results

Parameters:
Table 1 provides the parameters for the OFDM signaling.

Table 1 OFDM Parameters

OFDM Size	1024
Carrier Frequency	2.35 GHz
Bandwith	11.2 MHz

The channel gains are generated using the channel parameters provided in [1]. For fixed or nomadic RSs, the small scale fading is simulated using the SUI fading channel models. For mobile scenarios, e.g., at high speeds with large Doppler shifts, we resort to the legacy channel models.

We include several system parameters in Table 2.

Table 2 System parameters

Number of BSs	19
Number of Sectors per cell	3
BS separation	750 m
BS Tx Power	43 dBm (~19.95 W)
BS antenna	3-sector antenna with 20 dB front-to-back ratio
Height	25 m
Min RS-Rs and RS-BS separation	144 m
RS Tx Power	27.78 dBm (~600 mW)
RS antenna	Omni antenna (-1 dB gain)
Height	15 m
Thermal Noise Density	-174 dBm

RS preamble selection:
Each RS is required to generate a number of potential candidates for the preamble indices based on their measurements. The following method is studied:
     During the preamble selection period:

1. After each preamble symbol, calculate the correlation coefficient using (1)
2. After a specified number of frames, determine the PN index with the largest correlation coefficient. Get this PN sequence's segment_ID, which is 0, 1 or 2
3. To ensure that the RS employs a different set of OFDM tones for preamble transmission, determine those PN indices whose segment_IDs are not equal to the segment_ID determined in the previous step
4. Generate a subset of PN sequence indices which consists of those with the signal-to-interference metric given by (2) below some threshold

A critical step in this method is the number of potential candidates obtained at step 4.

Figure 2 plots the cumulative distribution function of the interference metric (2) obtained over *F=100* Frames (5 msec). It is seen that the interference in terms of correlation has a sharp CDF. For example, 94% of the available PN sequences results in a value less than 0.02 and about 84% results in a value less than 0.01. Hence, we have sufficient number of potential PN candidates for a dynamic PN index allocation.

Figure 2 CDF of interference metric in (2)

Nortel proposal on RS preamble selection suggests the feed-back of N preamble candidates to the BS and letting the BS finalize the RS index assignment. Hence, it is possible to avoid preamble collisions, i.e., the existence of neighbor RSs with the same PN index.

On the other hand, we can leave the PN index selection to the individual RSs. One way to do is to let each RS choose the PN index with the smallest interference metric given by (2) and having a segment_ID different from the one with the highest interference metric (see step 3 of the preamble selection method). We simulate the collision rate with this method assuming 10 RSs per cell. For this case, we calculate the interference by averaging (3) as

$$\bar{\gamma}_l[f] = \begin{cases} \gamma_l[0] & f = 0 \\ (1-\beta)\bar{\gamma}_l[f-1] + \beta\gamma_l[f] & f = 1,\ldots,F-1 \end{cases}$$

where $\beta = 1/(f+1)$. We set threshold to 10 dB and $F=5$. Thus, if $\bar{\gamma}_l[F-1] > 10$ dB for some PN index, the RSs using the same PN sequence and having the signal-to-interference ratio larger than this threshold is assumed to result in a PN collision. Table 2 provides the collusion rates in the case of 100 and 300 mobile stations per cell. We observe that even in this individual PN index assignment, the collision rates can be very low.

Table 3 Collusion Rate

# of RSs/cell	# of MSs/cell	Collision rate
10	100	0.00063
10	300	0.00095

Conclusions

Based on the above simulation, with the proposed dynamic preamble index assignment method, we can have a large set of potential PN sequence candidates.

Proposed text change

RS preamble measuring and selection

[Add the following section]

6.3.9.16 Network entry and initialization

6.3.9.16.1 RS network entry and initialization

6.3.9.16.1.1 Preamble selection

The preamble selection operation is only applicable to the RS which is configured to transmit 802.16d/e preamble to facilitate MS's cell selection.

During RS initial network entry, a RS needs to perform the cell selection as a MS does. If a RS is configured to transmit 802.16d/e preamble, this network entry procedure can be enhanced to enable RS assistant preamble PN sequence selection. The procedure includes the following steps:
- A RS maintains a table with each entry contains preamble index, corresponding PN sequence and strength
- A RS shall measure each preamble listed in the table
- The strength of each preamble is recorded in the table for the corresponding entry
- This measurement may take relative long time to minimize the impact of fading

- When the measurement procedure is finished (e.g., reach the required number of frames and so on), the RS may use certain criteria to determine its serving station (MMRBS or a RS)
- The RS uses the same table to determine the candidate preamble pool for purpose of a preamble selection for its own transmission after it assumes RS function
    i.   The candidate preambles in the candidate pool are those preambles whose strengths measured by this RS are lower than a pre-defined threshold
    ii. The RS then randomly selects N preambles from the candidate pool and reports to its MMRBS (may via other RS(s)) using preamble selection TLV in REG-REQ message. The selected preambles are indicated by preamble index
    iii. The MMRBS may assign a preamble based on information from the list reported by this RS and information such as preamble currently used within the cell and by its neighbor cell (assume this information can be shared by neighbor MMRBS through backhaul) and signal the determination to the RS through REG-RSP message

MAC management message modification

REG_REQ/RES is modified to include candidate preamble index TLV and preamble assignment.

[Insert the following text to the end of section 6.3.2.3.7 in Page 56]

The REG-REQ may include the following TLV:

    Preamble selection
    This TLV is used by a RS to indicate the preamble candidates to MMRBS.

[Insert the following text to the end of section 6.3.2.3.8 in Page 58]

The REG-RSP may include the following TLV:

    Preamble selection
    This TLV is used by a MMRBS to indicate the preamble assignment to a RS ..

[Add one type in Table 369a in page 685 of IEEE std 802,16e-2005]

Type	Parameter
45	Preamble selection

[Add a new section 11.7.27 as described]

11.7.27 Preamble selection

This field in REG-REQ message is used by a RS to report suggested preamble indexes to a MMRBS for the purpose of selection of a preamble to be used by the RS after it assumes a RS function.

This field in REG-RSP message is used by a MMRBS to indicate to a RS regarding the preamble assigned.

Type	Length	Value	Scope
45	N in REG-REQ (N is a	Each byte is used to indicate a	REG-REQ/RSP

	parameter broadcast by MMRBS) 1 in REG-RSP	preamble index
