**Abstract**  
This contribution provides a simple method of designing the RS amble sequence for the purpose of synchronization, channel estimation, carrier frequency estimation. The RS amble sequence should have properties very similar to the frame start preamble to minimize the impact on the existing standard and also enable reuse of existing technology defined for SS/MS receiver at the RS receiver.

**Purpose**  
For discussion and approval of inclusion of the proposed text into the P802.16j baseline document.

**Notice**  
This document has been prepared to assist IEEE 802.16. It is offered as a basis for discussion and is not binding on the contributing individual(s) or organization(s). The material in this document is subject to change in form and content after further study. The contributor(s) reserve(s) the right to add, amend or withdraw material contained herein.

**Release**  
The contributor grants a free, irrevocable license to the IEEE to incorporate material contained in this contribution, and any modifications thereof, in the creation of an IEEE Standards publication; to copyright in the IEEE’s name any IEEE Standards publication even though it may include portions of this contribution; and at the IEEE’s sole discretion to permit others to reproduce in whole or in part the resulting IEEE Standards publication. The contributor also acknowledges and accepts that this contribution may be made public by IEEE 802.16.

**Patent Policy and Procedures**  
The contributor is familiar with the IEEE 802.16 Patent Policy and Procedures [http://ieee802.org/16/ipr/patents/policy.html](http://ieee802.org/16/ipr/patents/policy.html), including the statement "IEEE standards may include the known use of patent(s), including patent applications, provided the IEEE receives assurance from the patent holder or applicant with respect to patents essential for compliance with both mandatory and optional portions of the standard."
A method of designing the RS amble sequence

1. Introduction
Based on the frame structure accepted by the baseline document, a RS amble is transmitted for the purposes as follows:

1) Downlink synchronization: RS amble can be used by a relay station (RS) to obtain the time synchronization, carrier frequency estimation and channel response estimation.

2) Monitor: enable other RS(s) and BS(s) to monitor the RS(s) and BS(s) in their coverage areas.

RS amble sequence should have properties very similar to the frame start preamble to minimize the impact on the existing standard and also enable reuse of existing technology defined for SS/MS receiver at the RS receiver.

The proposed methods for designing RS amble sequence are listed as follows:

1) RS amble is to use the same preamble sequence specified for IEEE 802.16e. The differentiation between the access zone amble and the relay zone amble should take place based on the FCH and MAPs following the preamble. However, this solution will cause problems since MSs could detect the same preamble twice in one frame, extending all the related network entry procedures.

2) RS amble is reusing the same PN sequence but allocating to the new relay amble sequence different (lower) amplitude. However, in the high mobility environment it could be expected that fast-fading could cause significant variation in path loss across the subframe that differentiation through amplitude will not be reliable.

3) Spliting the pool of 114 PN sequences into two smaller PN sub-pools: one allocated for BSs and another one re-allocated for RSs. This solution has the disadvantage of a relative small pool of RS sequences.

4) The relay amble series are obtained by reversing the corresponding preamble series in IEEE802.16e 8.4.6.1.1 for FFT size of 2048 and 1024. However, this solution will cause problems that one originality preamble can only produce one RS amble.

2. Detail
This contribution introduces a method for designing RS amble modulation series, avoiding the drawbacks related to the other solutions outlined above.

BS firstly uses the method proposed in this contribution and the threshold limit value (}
The procedure includes the following steps:

1) The BS circle-shifts the original preamble modulation series 

\[ P_{N_j,i} = 0,1,...,1 \] (specified in 8.4.6.1.1 in IEEE 802.16-2005) \( j \) bit \((j \text{ is between } 0 \text{ and } 567, 283, 143, 35 \text{ respectively for FFT Size of } 2048, 1024, 512, 128)\)

and obtains the new sequence of the \( P_{N_j,i} = 0,1,...,1 \).

2) The BS computes the coefficient of cross-correlation between \( P_{N_j,i} \) and \( P_{N_i} \).

The BS selects the \( P_{N_i,k} \) sequence based on (1).

\[ |P_{N_j,i} P_{N_k,i}| TLV_j \]  

\( TLV \) is a threshold limit value (TLV) of the coefficient of cross-correlation. The value of \( TLV \) decides the new amble sequence’s interference to original preamble sequence. In general, \( TLV \) is set to be zero.

3) The BS computes the coefficient of cross-correlation between \( P_{N_i,n} \) and \( P_{N_i,m} \).

The BS selects the \( P_{N_i,n} \) sequence based on (2).

\[ |P_{N_i,n} P_{N_i,m}| TLV_2,n m n \]  

\( TLV_2 \) is a TLV of the coefficient of cross-correlation. The value of the \( TLV_2 \) decides the interference level between one sequence and another sequence, both sequences are contained in \( P_{N_i,k} \). In general, we should set the value of \( TLV_2 \) lower than maximum cross-correlation of original Preambles.
4) The BS computes the coefficient of cross-correlation between $PN_i^d$ and $PN_i(0)$. The BS selects the $PN_i^{\*t}$ sequence based on (3).

$$\begin{bmatrix}
    PN_i^d & PN_i(0) \\
    TLV_i & x_i, x_i, x_i, TLV_i, n, \ldots, \ldots, 0
\end{bmatrix}$$

$TLV_3$ is a TLV of the coefficient of cross-correlation. The value of the $TLV_3$ decides the interference level between sequences obtained from $PN$ and another sequences obtained from $PN$. All those sequences should satisfy equation (1) and (2). In general, we should set the value of $TLV_3$ lower than maximum cross-correlation of original Preambles.

The BS saves all $PN_i^{\*}$ sequences as RS amble pool. The $i$ is related to the indexes of BS’s Cell and BS’s Segment.

After the RS completes the procedure of initial network entry, the BS to which the RS attached selects a RS amble sequence which has not assigned to the other RSs from RS amble pool and assigns it to currently RS using a message. If there is no usable RS amble in pool, the BS can change the value of $TLV_3$ and creates new ambles to the RS amble pool.

The RS amble modulation series in pool have the following properties:

1) The new RS amble modulation series have the same PAPR performance and amplitude as the original preamble sequences.

2) The cross-correlation between new RS amble series and the original preamble is zero; the cross-correlation between different RS amble sequences obtained by circle-shifting the same preamble series is lower than maximum cross-correlation of original preambles; the cross-correlation between RS amble sequences obtained by circle-shifting different preamble series is lower than maximum...
cross-correlation of original preambles.

3) The relay amble series has a simple relationship with the corresponding preamble series and is easy to be implemented.

4) The number of new RS amble can be changed by changing the Threshold Limit Value (TLV).

3. Specific text changes

8.4.6.1.1.3 Relay amble

The BS obtains the relay amble series $P_{N_k}^i, i = 0, 1, ..., 113$ from $P_{N_j}^i, i = 0, 1, ..., 113$ which is obtained by circle-shifting the corresponding preamble series (specified in 8.4.6.1.1 in IEEE802.16-2005) $j$ bit ($j$ is between 0 and 567, 283, 143, 35 respectively for FFT Size of 2048, 1024, 512, 128) through selecting by using $Y_{LW}, TLV_2$ and $TLV_3$. The values of $TLW, TLV_2$ and $TLV_3$ are determined by simulation in advance and the practical measurements.

The procedure includes the following steps:

1) The BS selects $P_{N_k}^i$ from $P_{N_j}^i$ based on equation (1_XXX).

\[ |P_{N_i}^j P_{N_k}^i TLW, k l | \] ...................................... (1_XXX)

Where $TLW$ is set in advance. Generally, $TLW$ is set to be zero.

2) The BS selects $P_{N_m}^i$ from $P_{N_k}^i$ based on equation (2_XXX).

\[ |P_{N_i}^n P_{N_m}^i TLV_2, n m, n, m k | \] .................................. (2_XXX)

Where $TLV_2$ is set in advance. Generally, $TLV_2$ is lower than maximum cross-correlation of original Preambles.
3) The BS selects $\mathbf{P}_n^{R_i}(t)$ from $\mathbf{P}_n(t)$ based on equation (3_\text{xxx}).

\[
|\mathbf{P}_n^{R} t, \mathbf{P}_n(t)|, TLI3, i, x, i, x, 0, 1, 1, 3t, n \ldots \ldots \ldots \ldots (3_{\text{xxx}}) .
\]

Where $TLI3$ is set in advance. Generally, $TLI3$ is lower than maximum cross-correlation of original Preambles.

The BS saves all the $\mathbf{P}_n^{R_i}$ sequences obtained through above procedures as RS amble pool, where $i$ is related to the index of BS’s IDcell and Segment. After the RS completion the initial network entry procedure, the BS to which the RS is attached selects a RS amble sequence which has not assigned to the other RS from RS amble pool and assigns this amble to the RS through the message in Table 1_xxx.

</tbody>
</table>

The BS only informs the RS the bits of circle-shift instead of the RS amble sequences. RS receives the bits of circle-shift and correspondingly circle-shifts the preamble obtained during initial network entry. After these procedures the RS obtains its amble sequence.

When there is no RS amble in pool, the BS can changes the values of $YL$, $TLI2$, and $TLI3$, and creates new RS amble sequences to RS amble pool.

Both the value of $TLI2$ and $TLI3$ should be lower than the maximum cross-correlation of original Preambles. The maximum cross-correlation of original preambles is listed in table 2_xxx.
