Title	<b>Absurdly late contribution: Appendix A.2 rewrite</b>
Date Submitted	2001-09-05
Source(s)	<p>Nico van Waes      [<a href="mailto:nico.vanwaes@nokia.com">mailto:nico.vanwaes@nokia.com</a>]</p> <p>Jori Arrakoski      [<a href="mailto:jori.arrakoski@nokia.com">mailto:jori.arrakoski@nokia.com</a>]</p>
Re:	80216ab-01_06r1
Abstract	<p>This contribution consists of clauses re-organizing and extending the preliminary interference study in Annex A.2 The main extention comes in the form of a description of other services in the 5GHz bands an analysis of the mesh mode of 802.16b air interface standard in 5 GHz. The text is structured around a separation between the PMP and mesh analysis as these different network topologies have significantly different properties.</p> <p>As there is no seperate task group working on a interference and co-existence document for license-exempt, it is important to study the interference and co-existence issues surrounding this standard and maintain it as an annex to the draft standard, because it adds weight to the arguments and efforts to get this standard accepted world-wide.</p> <p>This document is not a standalone document but should be used in parallel with the related comments giving definite instructions.</p>
Purpose	Adopt the text proposed to the 802.16ab-01/01 draft to expand the interference analysis.
Notice	This document has been prepared to assist IEEE 802.16. It is offered as a basis for discussion and is not binding on the contributing individual(s) or organization(s). The material in this document is subject to change in form and content after further study. The contributor(s) reserve(s) the right to add, amend or withdraw material contained herein.
Release	The contributor grants a free, irrevocable license to the IEEE to incorporate material contained in this contribution, and any modifications thereof, in the creation of an IEEE Standards publication; to copyright in the IEEE's name any IEEE Standards publication even though it may include portions of this contribution; and at the IEEE's sole discretion to permit others to reproduce in whole or in part the resulting IEEE Standards publication. The contributor also acknowledges and accepts that this contribution may be made public by IEEE 802.16.
Patent Policy and Procedures	<p>The contributor is familiar with the IEEE 802.16 Patent Policy and Procedures (Version 1.0) &lt;<a href="http://ieee802.org/16/ipr/patents/policy.html">http://ieee802.org/16/ipr/patents/policy.html</a>&gt;, including the statement "IEEE standards may include the known use of patent(s), including patent applications, if there is technical justification in the opinion of the standards-developing committee and provided the IEEE receives assurance from the patent holder that it will license applicants under reasonable terms and conditions for the purpose of implementing the standard."</p> <p>Early disclosure to the Working Group of patent information that might be relevant to the standard is essential to reduce the possibility for delays in the development process and increase the likelihood that the draft publication will be approved for publication. Please notify the Chair &lt;<a href="mailto:r.b.marks@ieee.org">mailto:r.b.marks@ieee.org</a>&gt; as early as possible, in written or electronic form, of any patents (granted or under application) that may cover technology that is under consideration by or has been approved by IEEE 802.16. The Chair will disclose this notification via the IEEE 802.16 web site &lt;<a href="http://ieee802.org/16/ipr/patents/notices">http://ieee802.org/16/ipr/patents/notices</a>&gt;.</p>

# Absurdly late contribution: Appendix A.2 rewrite

*Comment 1 related text follows:*

## **A.2 License-exempt**

### **A.2.1 Interference mitigation and sharing mechanisms**

In this clause a number of license exempt interference mitigation and sharing mechanisms is identified. Two categories are considered: mechanisms that fall within the scope of the IEEE 802.16b standard and methods that fall outside that scope.

Within the scope of the IEEE 802.16 standard, three methods are identified: dynamic frequency selection (DFS), which is not mandated by the standard, but mandated by some regulatory bodies such as ERC [B54]; transmit power control, which is mandated by the standard [REF???? ] and by some regulatory regions such as ERC [B54]; and ephemeris transmit interruption, which is mandated by neither.

Outside the scope of the IEEE 802.16 standard, two methods are identified: antenna directivity and antenna polarization.

#### **A.2.1.1 Dynamic frequency selection**

As frequency planning is not practical in licensed-exempt bands, DFS can be used to avoid assigning a channel to a channel occupied by another system. DFS is generally based on comparison of a C/I threshold against idle time RSSI measurements. DFS is predominantly effective to combat interference from and to ground based systems, such as WLANS, RTTT, radar and other IEEE 802.16b compliant systems. It is generally ineffective to combat interference from and to airborne systems, such as airborne radars and satellites.

#### **A.2.1.2 Transmit power control**

With power control, the transmitter EIRP is reduced according to the link margin. Shorter link ranges hence result in lower transmitted power levels. For PMP systems, the average EIRP will hence typically be several dB's below the legal limit assuming that SSs are spread throughout the coverage area. For mesh systems, this means that EIRP values decrease rapidly as customer deployment density increases. Therefore, an estimate of total interference within the footprint could be as much as 'n' dB below the reference value. As power control is also influenced by C/I levels, the use of TPC with DFS, where possible, tends to result in the most effective interference mitigation.

#### **A.2.1.3 Ephemeris transmit interruption**

1 Earth Resources Satellites operate at very precise orbits, therefore, the Ephemeris (orbital position correlated to time)  
2 of the satellites can be calculated with great accuracy. If an Ephemeris calculator is included in the basestations, and/  
3 or in the networks, the stations could be muted during the satellite pass. This would amount to a muting time of  
4 approximately 15 seconds per satellite pass-typically 5-10 days per pass. Coupled with antenna directivity, this fea-  
5 ture would allow virtually any number of stations to operate within the satellite footprint.  
6

#### 7 8 **A.2.1.4 Antenna directivity** 9

10 Antenna directivity, in horizontal but especially in vertical direction can significantly reduce an FWA's interference  
11 potential and resilience. Vertical directivity especially reduces the interference caused to satellite systems, which are  
12 designated primary users of part of the addressed bands. It also can significantly help reduce interference to and from  
13 indoor WLAN systems. Horizontal directivity significantly reduces the probability of interference to other systems  
14 (assuming interference is mainly caused in the main lobe), but tends to increase the severity of the interference, as the  
15 energy in the main lobe is generally higher.  
16  
17

#### 18 19 **A.2.1.5 Antenna polarization** 20

21 Antenna cross-polarization in the 5GHz band can achieve an isolation of up to 15 dB in LOS, but reduces signifi-  
22 cantly in near-LOS and NLOS environments. Most deployments use both horizontal and vertical polarization (circu-  
23 lar polarization is not as common in currently known systems) to maximize spectral re-use. Polarization hence has the  
24 potential to provide some isolation between differently polarized systems, especially in LOS, but given the opera-  
25 tional needs and implementation of most systems in the targeted spectrum, the effectiveness will be mostly marginal.  
26  
27

#### 28 29 **A.2.2 Services in the 5 GHz band** 30

31 In this section a short description of the systems and services in the 5GHz bands is given together with the necessary  
32 parameters for the subsequent interference analysis. This includes assumptions on parameters of IEEE 802.16b com-  
33 pliant systems that are beyond the scope of this standard.  
34

35 It is important to note that, throughout this study, the use of 6 dBW max. EIRP is assumed for all parts of the spec-  
36 trum with a backoff of only 3 dB for WLAN type devices. In a practical OFDM system, the backoff is in the order of  
37 at least 6 dB minimum, whereas the rules commonly specify at most 0 dBW maximum mean EIRP [B55] or 6dBW  
38 maximum peak EIRP [B19] for fractions of the band. It should hence be understood that this study errs on the side of  
39 caution in how much interference can be tolerated.  
40

#### 41 42 **A.2.2.1 IEEE 802.16b PMP system** 43

44 TBD  
45

#### 46 47 **A.2.2.2 IEEE 802.16b mesh system** 48

49 The Mesh deployment scenario is abstracted into a regular hexagonal shape as shown in Figure 1. On each corner of  
50 each hexagon, one mesh node is located. By parameterizing the distance between a set of neighboring nodes, different  
51 mesh deployment density scenario's can relatively easily be analyzed.  
52  
53  
54  
55  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65

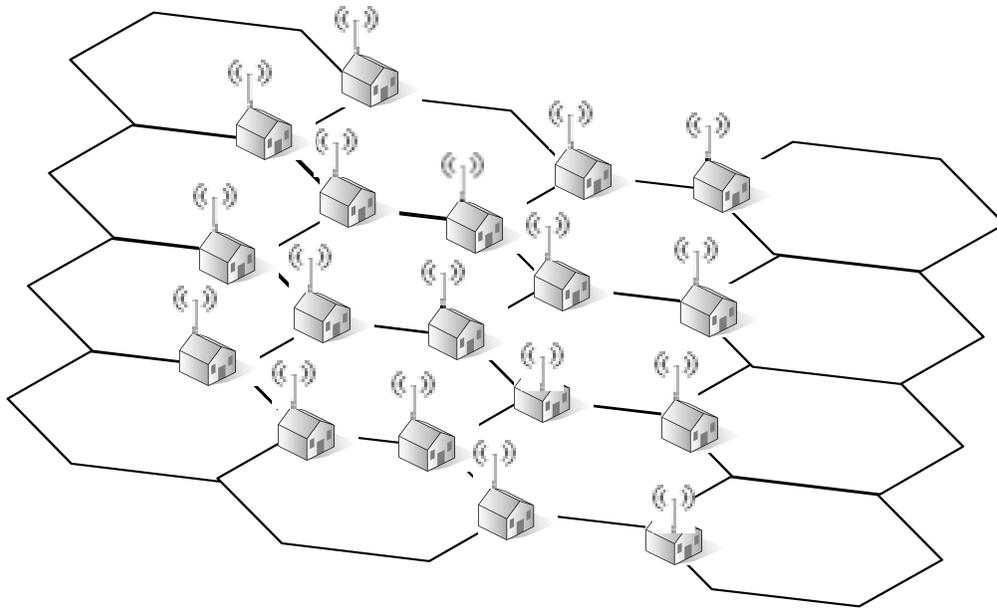

Figure 1—IEEE 802.16b mesh deployment model

If the distance between two nodes is denoted  $r$ , then from each node, we have 3 neighbors at distance  $r$ , 6 nodes at distance  $2r\sqrt{3}/2$ , 3 nodes at distance  $2r$ , 6 nodes at distance  $3r\sqrt{3}/2$ , 6 nodes at distance  $3r$ , 12 nodes at distance  $\sim 4r\sqrt{3}/2$ , 3 nodes at distance  $4r$ , 12 nodes at distance  $\sim 5r\sqrt{3}/2$  etc.

Mesh devices that are close to each other cannot transmit at the same time on the same channel. This is normally defined in terms of extended neighborhoods, which comprises all nodes within two hops from the transmitting node. For modeling purposes, it is assumed that if a node is transmitting, all other nodes on the three hexagons that intersect on that node are silent. This translates into all nodes within a distance of  $2r$  being silent.

In Table 1, the topology and traffic assumptions are shown. The Tx activity of a node depends heavily on its position in the network, i.e. on how much traffic must be forwarded from/to other nodes, and how active neighboring nodes are. To keep the analysis simple, an average of 5% is assumed (This based on the current average household internet usage of 30 minutes per day, as well as the activity probability during this on-time).

Table 1—Tx activity parameters

Parameter	Value
Typical hops/packet	2
Total Tx activity	5%

Based on this model, the background interference at any node can be computed, which can be added to the interference from the node in question, resulting in the overall system interference.

#### A.2.2.2.1 Antenna parameters

1 The mesh device is assumed to be using omni-directional antennas at all times, which is a worst-case assumption, as  
 2 non-broadcast communications between nodes could be performed with smart antennas to reduce overall interfer-  
 3 ence.  
 4

5  
 6 It is extremely important to notice that the mesh device is by necessity a roof-mounted device, as it must extend cov-  
 7 erage in all directions. In contrast to PMP Subscriber System (SSs), which are typically installed under the eaves, the  
 8 amount of vertical scattering, which is harmful to both ground-based WLAN devices and satellites, is significantly  
 9 less despite the lack of horizontal directivity. This is due to the relatively good probability of clear line-of-sight of the  
 10 nodes to each other due to their individual mounting location as well as the significantly shorter distances to each  
 11 other than a PMP SS typically enjoys to its BS. On top of this, the variation in heights of the nodes' antennas is negli-  
 12 gible, whereas a PMP BS typically is installed at much greater height than its SUs, the result of which is that SSs are  
 13 generally installed with some vertical tilt, which worsens their illumination of satellites.  
 14

15  
 16 For these reasons, no extra scattering in the vertical direction is assumed for this evaluation besides the antenna pat-  
 17 tern.  
 18

19  
 20  
 21  
 22 **Table 2—Antenna parameters**

Parameter	Value
Mounting	Outdoors/rooftop
Gain (Horizontal omni-directional)	8 dBi @ 90° -22 dBi @ 0 - 30° -15 dBi @ 30 - 50°
Polarization	vertical

23  
 24  
 25  
 26  
 27  
 28  
 29  
 30  
 31  
 32  
 33  
 34  
 35  
 36 As shown in Table 2, the antenna is an 8dBi gain omni-directional antenna with a -22 dBi vertical gain and worst-case  
 37 -15 dBi between 30 and 50° from vertical.  
 38

#### 39 **A.2.2.2.2 Mandatory mode Radio parameters**

40  
 41 Although 5 and 10 MHz channelization are also defined, the focus here is on the mandatory 20 MHz channelization,  
 42 which gives the worst case scenarios.  
 43

44  
 45 It is important to note that the use of 6 dBW max. EIRP is assumed for all parts of the spectrum with a backoff of only  
 46 3 dB. In a practical OFDM system, the backoff is in the order of at least 6 dB minimum, whereas the rules commonly  
 47 specify at most 0 dBW maximum mean EIRP [B55] or 6dBW maximum peak EIRP [B19] for fractions of the band.  
 48 It should hence be understood that the analyses err (by 3 to 10 dB) on the side of caution in how much interference  
 49 can be tolerated.  
 50

51  
 52  
 53 **Table 3—Relevant Radio parameters I**

Parameter	Value
Transmit Power	28 dBm (i.e. 36 dBm max EIRP) with dynamic power control
20 dB bandwidth	21 MHz
Peak-to-Average Power ratio	3 dB

The Rx Sensitivity and C/I parameters for the code rates defined in Table 175 and Table 195 are temporarily, as they are currently not yet defined in the IEEE 802.16b standard.

They are estimated using the formula:

$$R_{x_{sens}}(dBm) = K \cdot T_0(dBm) + 10\log(BW_{-26dB}) + NF(dB) + SNR_{avg} + margin$$

The thermal noise is  $K \cdot T_0 = -174dBm$  and the noise figure is chosen to be  $NF = 7dB$ . The margin is assumed to be 5dB, consistent with [B47]. This leaves us with  $R_{x_{sens}}(dBm) = SNR_{avg} - 88.5$ . SNR's are guesstimated from several preliminary studies

**Table 4—Relevant Radio parameters II**

Modulation	Coding Rate	SNR <sub>avg</sub> (dB @ 0.1%PER)	Rx Sensitivity (dBm @ 0.1% PER)
BPSK	1/2	7	-82
	3/4	13	-76
QPSK	1/2	10	-79
	3/4	17	-72
16QAM	1/2	19	-70
	3/4	25	-64
64QAM	2/3	30	-59
	3/4	40	-49

For the purpose of analytical full network interference analysis, the receiver sensitivity of the mesh system is chosen to be -75 dBm, an average of the modulation and coding mode sensitivities up to rate 1/2, 16-QAM, which will be the most likely used in practical deployments.

### A.2.2.3 EESS and FSS

Two types of satellite services are deployed in the 5 GHz; fixed satellite service (FSS) and earth exploratory satellite systems (EESS) services, EESS services are provided by two distinct types of satellite: Altimeter satellites and SAR satellites.

#### A.2.2.3.1 Altimeter satellites

1 The characteristics of altimeter satellites have been derived from [B46].  
 2  
 3  
 4

5 **Table 5—Altimeter satellite characteristics**  
 6

7 <b>Parameter</b>	8 <b>Value</b>
9 Bandwidth	320 MHz
10 Rx sensitivity	-88 dBm
11 On-axis Antenna gain	32.5 dBi
12 Off-axis Antenna gain	$10^{3.25(\sin(\varphi)/\varphi)^2}$ a
13 Antenna size	1.2 m
14 height	1344 km
15 Input loss = Output loss	1 dB
16 coverage	$\varphi \in [-60^\circ, 60^\circ]$
17 Bandwidth	320 MHz

18 a.  $\varphi$  is the angle between the vertical and the direction of the ground-based device

Antenna Type	Planar phased array 0.5m x 16.0m	Planar phased array 1.8m x 3.8m	Planar phased array 0.7m x 12.0m	Planar phased array 0.7m x 12.0m
Antenna Peak Gain	42.2 dBi	42.9 dBi	42.7/38 dBi (full focus/beam-spoiling)	42.7/38 dBi (full focus/beam-spoiling)
Antenna Median Sidelobe Gain	-5 dBi	-5 dBi	-5 dBi	-5 dBi
Antenna Orientation	30 deg from nadir	20-38 deg from nadir	20-55 deg from nadir	20-55 deg from nadir
Antenna Half-power Beamwidth	8.5 deg (El), 0.25 deg (Az)	1.7 deg (El), 0.78 deg (Az)	4.9/18.0 deg (El), 0.25 deg (Az)	4.9/18.0 deg (El), 0.25 deg (Az)
Antenna Polarization	Linear horizontal/ vertical	Linear horizontal/ vertical	Linear horizontal/ vertical	Linear horizontal/ vertical
System Noise Temperature	550 K	550 K	550 K	550 K
Image swath width	50 km	20 km	16 km/ 320 km	16 km/ 320 km

For both the SAR imaging missions and the topographic missions, a minimum signal-to-noise ratio (SNR) is defined, below which the radar image pixels, and/or differential phase measurements are unacceptably degraded. The following interference criteria are from ITU-R JWP 7-8R:

- 1 • the degradation of the normalized standard deviation of power received from a pixel should be less than 10% in
- 2 the presence of interference;
- 3 • the aggregate interference power-to-noise power ratio (corresponding to a pixel SNR of 0 dB) should be less than
- 4 -6 dB;
- 5 • These levels may be exceeded upon consideration of the interference mitigation effect of SAR processing dis-
- 6 crimination and the modulation characteristics of the radiolocation/ radio-navigation systems operating in the
- 7 band;
- 8 • The maximum allowable interference level should not be exceeded for more than 1% of the images in the sensor
- 9 service area for systematic occurrences of interference and should not be exceeded for more than 5% of the
- 10 images in the sensor service area for random occurrences of interference.
- 11
- 12

13  
14 The data loss criteria have been fully utilized to achieve sharing with the radio determination service. This study  
15 therefore uses the degradation interference criteria to derive the sharing constraints on FWA devices. Assuming that  
16 the interfering signal distribution is white Gaussian noise the maximum acceptable interference signal is indicated in  
17 the table below:  
18

19  
20  
21 **Table 7—Typical Spaceborne Imaging Radar Characteristics**  
22

23 24 25 <b>Parameter</b>	26 27 28 <b>Value</b>			
29 30 31 Noise (dBW)	-129.5	-113.8	-113.8	-122.7
32 33 Minimum Desired Signal (dBW)	-189.7	-198.6	-187.1	-187.0
34 35 36 Maximum Acceptable Interfering signal (dBW)	-135.5	-119.8	-119.8	-128.7
37 38 Receiver Bandwidth (MHz)	9.8	356.5	356.5	46

48 49 50 Ground Illumination Area	93 km (elevation), 2.2 km (azimuth)	At 20° from nadir: 20 km (elevation), 8.7 km (azimuth)	At 20° from nadir: 40 km (elevation) 2 km (azimuth)	At 20° from nadir: 40 km (elevation) 2 km (azimuth)

### 51 52 53 **A.2.2.3.3 FSS satellites** 54

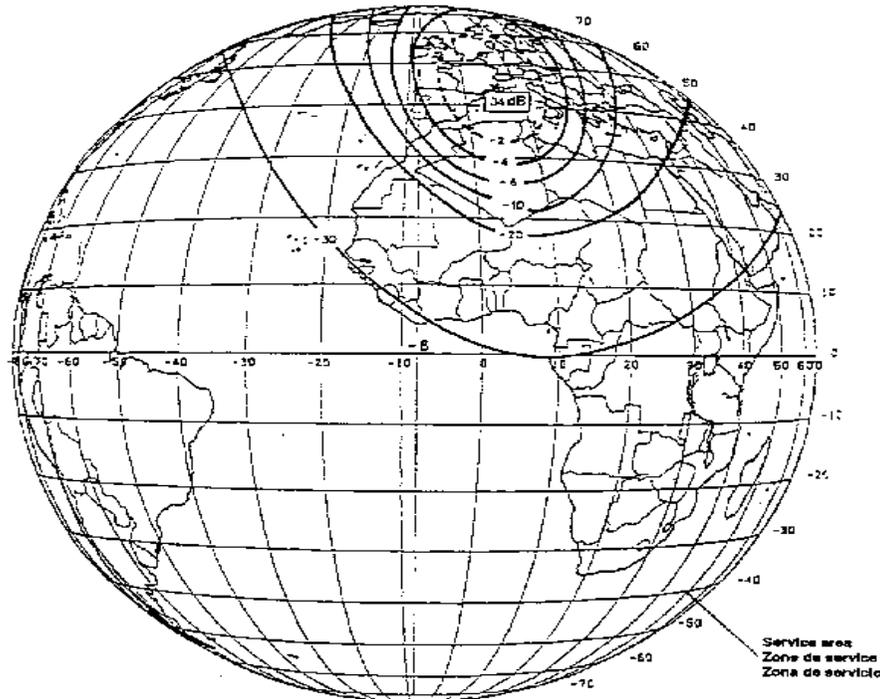

55 The characteristics of Fixed Satellite Service satellites have been derived from [B46].

56 The maximum allowable interference power spectral density tolerated by FSS satellites is given by

$$57 \quad p = -42 + (G/T) - \gamma \quad \text{dBW/Hz}$$

58 in which  $G$  is the gain of the satellite antenna,  $T$  the noise temperature ( $G/T$  is termed the merit factor), and  $\gamma$  the link  
59 gain. FSS satellites are geo-stationary and hence located at 36000 km, resulting in 199 dB pathloss. In the case of the  
60  
61  
62  
63  
64  
65

1 Telecom 3 network, which is used as example,  $\gamma$  is 0 dB, the total link equivalent noise temperature is 870 K, the gain  
 2 for the 'Metropole' spot is 34 dBi and the coverage area of this spot is all of Europe. G/T then becomes 4.6 dB.

#### 35 **A.2.2.4 WLANs**

36  
 37  
 38 The WLAN deployments considered here are the ETSI BRAN HIPERLAN/2 [B48] and IEEE 802.11a devices. Only  
 39 indoor deployments are considered in detail. It is clear that outdoor WLAN devices can generally not co-exist in the  
 40 same channel with FWA devices in the same geographical area. However, the use of DFS, as well as the fact that the  
 41 hotspot locations envisioned for outdoor WLAN deployments (such as airports and school campuses) do generally  
 42 not coincide with the residential areas Mesh devices are targeted towards, easily resolve this type of WLAN deploy-  
 43 ments.

#### A.2.2.5 RTTT

Road transport & traffic telematics (RTTT) devices[B51] are allocated in the band 5795-5805 MHz (2×5 or 1×10), with an extension band 5805-5815 MHz (2×5 or 1×10), which may be used on a national basis at multi-lane road junctions. These devices are split into the Road Side Unit (RSU) and the onboard unit (OBU), the parameters for which are shown in Table 10 and Table 11.

**Table 10—RTTT RSU Parameters**

Parameter	Value
Tx Power (max EIRP)	3 dBW
Rx sensitivity	-105 to -130 dBW <sup>a</sup>
Antenna gain	20 dB
C/I: 2 / 4 / 8 - PSK	6 / 9 / 12 dB
polarization	circular

a. This range is merely informative. The device must merely meet the manufacturer's claim.

Table 11—RTTT OBU Parameters (-35° to +35°)

Parameter	Value	
Class	A,B,C,D	E
Re-radiated subcarrier power (max EIRP)	-54 dBW	-44 dBW
Antenna gain	1 dB	
Rx sensitivity	-73 dBW	-70 dBW
C/I: 2 / 4 / 8 - PSK	6 / 9 / 12 dB	C/I: 2 / 4 / 8 - PSK
polarization	circular	polarization

In analyzing the compatibility between HIPERLANs and RTTT the basic approach taken is to use the Minimum Coupling Loss (MCL) technique to determine the necessary separation distances between the two systems.

Minimum coupling loss: 
$$L = P_t - \max \left\{ 10 \log \left( \frac{B_i}{B_{Rx}} \right), 0 \right\} - I_{Rx}$$

Where  $P_t$  = transmitter power

$B_{Rx}$  = receiver bandwidth (MHz)

$B_i$  = interferer bandwidth (MHz)

$I_{Rx}$  = tolerable interference at receiver (dBW)

Required separation distance:  $d = \frac{\lambda}{4\pi} 10^{pathloss/23}$  where *pathloss* = *L* + *Antenna and feeder gains and losses*

#### A.2.2.6 Radar

The radar parameters used in the radar analysis are taken from [B46],[B53]. In the analysis, the MCL technique described in clause A.2.2.5 will be used, with the exception that for the airborne radar (radar type B), a propagation exponent 2.0 instead of 2.3 is used.

**Table 12—Relevant radar parameters**

Parameter	Value				
	A	B	C	D	E
Radar type	A	B	C	D	E
Peak EIRP (dBW)	98.6	26	60	93	97
$BW_{\text{radar}}$ (MHz)	3	15	30	14	3
Antenna gain (dBi)	40	0	46	43	43
Tuning range (GHz)	5.30-5.60	5.70-5.80	5.40-5.82	5.25-5.85	5.60-5.65
Use	Transportable long range	Airborne	Fixed long range	Transportable multi-function	Fixed long range

### A.2.3 IEEE 802.16b PMP interference analyses

#### A.2.3.1 Coexistence with SAR satellites in middle UNII

The Wireless HUMAN Standard-based systems that will operate in the middle U-NII band (5.25-5.35 GHz) will have to share this band with a number of other systems (e.g., Earth Exploratory Satellite (active) Service (EESS) Synthetic Aperture Radars (SARs), Wireless HUMAN Standard-based systems, non-standard point-to-multipoint Broadband Fixed Wireless Access (BFWA) systems, terrestrial Radars, and IEEE 802.11a, 802.15 and HIPERLAN/2 Wireless LANs). As this is a License-Exempt (LE) band these diverse systems will often be operated in the same geographical area by different operators. Moreover besides having to meet local Regulatory requirements (e.g., in the USA the FCC Subpart E Requirements) the Wireless HUMAN Standard-based systems will also be called to meet global agreements; e.g., from the World Radiocommunications Conference (WRC).

What follows gives an indication of the interference that Wireless HUMAN based BFWA systems can cause to SARs operating in Middle U-NII band. In particular it has been shown by published results of ITU-R studies that BFWA antenna directivity is effective in minimizing interference to SAR-4, (e.g., USA ITU-R WP7C/24 Contribution). Table 13 shows that use of 6dB antenna directivity can decrease the SAR-4 interference by 4dB.

Note: The value of antenna directivity that should be specified requires trade-off studies with the other mechanism. SAR-4 is used because the SAR-4 system is more interference sensitive than SAR-3 and SAR-4, and the SAR-4 center frequency is 5.3GHz.

The SAR-4 Synthetic Aperture Radar scans a path from  $20^\circ$  to  $55^\circ$  from Nadir. This corresponds to Earth incident angles of  $21^\circ$  and  $60^\circ$ -which can be translated to angles of  $69^\circ$  and  $30^\circ$  with respect to the horizon. That is, any radiation from U-NII devices within that angular range could cause/contribute to satellite interference.

An approach that can be used in analyzing the interference potential from Middle U-NII BFWA systems into spaceborne SAR-4 receiver is to determine the worst case signal power received from a single BFWA transmitter at the spaceborne SAR. Then, the single interferer margin can be calculated by comparing the single BFWA interferer level

1 with the SAR-4 interference threshold. Knowing the SAR-4 footprint, the allowable density of active BFWA trans-  
 2 mitters can then be calculated, if a positive margin results from a single BFWA interferer.  
 3  
 4  
 5

6 **Table 13—Single U-NII BFWA to SAR-4 Interference**

 46  
 47 Table 13 shows the signal power at the SAR-4 receiver from a transmitter with power output of -6 dBW (24 dBm)  
 48 and an isotropic radiator with unity gain at all look angles. The space loss at angles of  $21^\circ$  and  $60^\circ$ , receive antenna  
 49 gain, polarization loss, scattering gain and satellite interference threshold are derived from ITU-R reports. The refer-  
 50 ence margin is the difference between the Signal Power at the Satellite Receiver and the Satellite Interference Thresh-  
 51 old. The negative margin numbers indicate that radiating an EIRP of 24 dBm toward the satellite will exceed the  
 52 interference threshold. Fortunately, real-world antennas do not exhibit unity gain at high elevation look angles, and  
 53 this feature can be used to mitigate interference  
 54  
 55

56 A conclusion that can be drawn is that antenna directivity, if properly utilized, will provide interference margin for  
 57 multiple transmitters. However, it should be noted that the satellite footprint is large (53 sq. km at  $20^\circ$  from Nadir and  
 58 208 sq. km at  $55^\circ$  from Nadir). Therefore, given the potential variables associated with the design, installation and  
 59 maintenance of the various unlicensed transmitters, antenna directivity alone may not be sufficient to assure non-  
 60 interference.  
 61  
 62  
 63  
 64  
 65

1 The margin calculation in Table 13 includes 3 dB polarization loss. The fact that most P-MP systems rely on polariza-  
 2 tion for maximizing channelization, as many as half of the U-NII transmitters in a given area could be transmitting on  
 3 each polarization. If so, the 3 dB polarization loss may not be fully realizable.  
 4

5  
 6 If the satellite were restricted to one linear polarization and the U-NII transmitters were restricted to the other linear  
 7 polarization, greater polarization isolation could be achieved. Given the operational needs of both services, this is  
 8 unlikely to happen.  
 9

## 10 **A.2.4 IEEE 802.16b mesh interference analyses**

### 11 **A.2.4.1 Interference to EESS and FSS**

#### 12 **A.2.4.1.1 Altimeter satellites**

13 The interference from one mesh node into the boresight of the SAR can be described by (see [B46])

$$14 \quad P_r = \frac{P_m G_m G_a \lambda^2}{(4\pi)^2 R^2} L$$

15 in which  $P_m G_m = 6dBm$  (28 dBm Output power - 22 dBi top lobe) is the EIRP of the mesh antenna in the vertical  
 16 direction,  $G_a = 32.5dBi$  the gain of the altimeter antenna,  $\lambda = 5.66cm$  the wavelength,  $L = -1dB$  the input loss of  
 17 the altimeter, and  $R = 1344km$  the lowest orbit.  
 18

19 From this we obtain a value for  $P_r = -132dBm$

20  
 21 The altimeter interference threshold is - 88 dBm; we can thus deduce that the altimeter can withstand the operation of  
 22 huge numbers of mesh devices simultaneously, since we have a 44 dB margin. Furthermore, the altimeter is built to  
 23 provide measurements mainly over oceans and is not able to provide accurate data when a significant amount of land  
 24 is in view of its antenna beam. From this analysis, it is clear that the altimeter will not suffer from the operation of  
 25 Mesh networks. However, for completeness, the number of mesh devices per square kilometer tolerable by the altim-  
 26 eter can be calculated.  
 27

28 The distance between the satellite and a mesh node under angle  $\phi$  is  $R \tan(\phi)$  km. Only freespace attenuation, which  
 29 ignores atmospheric properties (which further attenuate the signal, especially when  $\phi \gg 0$ ) has been considered.  
 30

31 For simplicity, the 3 mesh nodes that on average exist in one hexagon are assumed to all be in the centre point of the  
 32 hexagon. The hexagon grid then reduces to a square grid with 3 nodes every 2 times the distance of a single set of  
 33 nodes.  
 34

35 We then have:

$$36 \quad P_r = \sum_{r_1} \sum_{r_2} \frac{3P_m G_m G_a \lambda^2}{(4\pi)^2 R^2} L \left( 1 + 4A \sum_{r_1} \sum_{r_2} \sin^2 [2\phi(r_1, r_2)] \right) \quad \forall \sqrt{r_1^2 + r_2^2} < \frac{R\sqrt{3}}{2} \quad \phi = \arctan \left[ \frac{2\sqrt{r_1^2 + r_2^2}}{R} \right]$$

37 in which  $r_1$  and  $r_2$  enumerate over the square grid, and  $A$  is the activity factor. This derivation is easily computed  
 38 numerically. According to [B50], significantly less than 15%<sup>1</sup> of land is used for residential areas and normally a sig-  
 39 nificant fraction of the footprint covers water as well. Hence a Residential fraction of 0.05 is introduced, to simulate

```

**Figure 3—mesh interference code sample**

The result of the simulation, as shown above, is that over 30 million nodes can be supported under the footprint, with 6 dB in interference margin. In many cases shorter distances between the nodes will result in lower used power due to power control. Hence in practice many more nodes could be supported without violating the interference limit.

#### A.2.4.1.2 SAR satellites

In analogy with [B46], only the case for SAR-1 satellites is examined, since this provides the worst case analysis. However, contrary to this report, it will show that using mesh technology, an increase in network density actually reduces the interference into the SAR satellite, since the dynamic power-control reduces the power for shorter links. The receiver sensitivity is, as discussed in clause A.2.2.2.2, chosen to be -75 dBm.

As can be seen from Table 14, a mesh networks has limitations both on the maximum distance and maximum density of the network. The maximum distance that can be achieved by the mesh network using 4 Watts EIRP is about 1 km, which retains a margin of 10 dB to the interference threshold.

Deployments with distances between nodes of one km are however exceedingly sparse and not practical except in the very early stages of service rollout (i.e. when seeding the service area).

1 Reducing the distance increases the number of nodes, but reduces the necessary power levels, hence reducing the  
 2 overall interference into the satellite. Increasing the density, and hence the number of nodes to very high levels, up to  
 3 about one device per 92 m would still obtain tolerable interference levels. Deployment densities of this nature, espe-  
 4 cially in the areas of major interest to the satellite community (which to our understanding are mostly oceanic and  
 5 agrarian), are however extremely unlikely.  
 6

7  
 8 PMP systems do not enjoy the same advantage, as increased capacity needs are mostly met by increasing the number  
 9 of sectors on the base-station, keeping the EIRP on each SU constant. Interference in that case increases linearly with  
 10 the number of sectors deployed, and hence in practice linearly with the number of SUs installed on each basestation.  
 11 The limitations on the SU density are hence much sooner violated.  
 12

13  
 14 To allow an easier comparison with the WLAN results in [B46], Table 14 computes the number of Mesh devices that  
 15 can be situated in the SAR footprint without exceeding the interference limit.  
 16

17

 60 In Table 14, it is assumed that all Mesh devices are located in the boresight of the SAR satellite, which provides the  
 61 worst case scenario.  
 62

### 63 **A.2.4.1.3 FSS satellites**

1 The bandwidth of the Mesh device is 21 MHz (73.2 dBHz). The maximum allowable interference power spectral  
 2 density tolerated by the Telecom 3 network (see clause A.2.2.3.3) then becomes 27 dBW/Hz.  
 3

4 Appendix S8 of the ITU Radio Regulations [B49] gives the method to calculate the maximum interference power  
 5 produced by an earth station to a satellite receiver. When calculating the maximum interference power from Mesh  
 6 devices into a satellite receiver, we have to consider all the mesh devices under the satellite footprint as a single  
 7 source. This means that the source is not specifically located, and only the direct top lobe of the mesh antenna is taken  
 8 into account.  
 9  
 10

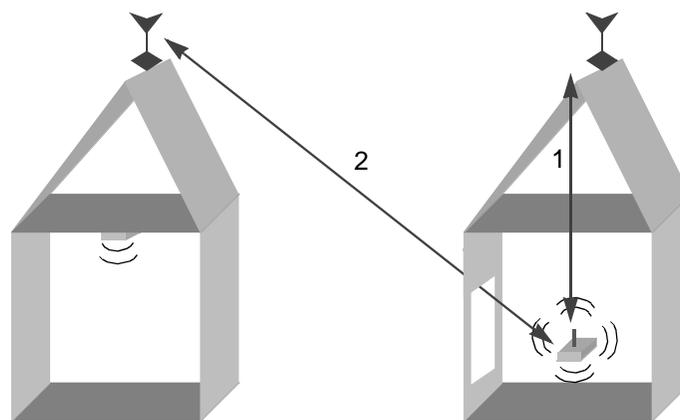

11  
 12 **Table 15—Tolerable mesh nodes for FSS operation**  
 13

Parameter	Value

 60  
 61 **Figure 4—Immediate neighbourhood scenario**  
 62

63  
 64 **A.2.4.2.1.1 'Same building' analysis (1)**  
 65

1 In the immediate neighborhood scenario, the interference from a Mesh node to a WLAN device in the same building  
2 is analyzed (link 1 in Figure 4).  
3

4 It is assumed for this scenario, that the distance between the Mesh node and the WLAN device in the same building is  
5 5 m. The structural isolation plus attenuation due to multipath/scattering is assumed to be 25 dB over that distance,  
6 based to Annex 2 of [B46]. Note that this is not the same as the average 13.4 dB assumed in [B46], since we consider  
7 only placement of Mesh devices on the roof, and not placement outside in general as in the outside WLAN case. This  
8 is likely to be a very modest value for a typical home with concrete ceiling and stone tile roofing. The total attenua-  
9 tion is then  $25 + 20 \cdot \log_{10}(4 \cdot \pi \cdot d \cdot f_0 / c) = 86$  dB. Given the radiation pattern of a Mesh node transmitting at full 28  
10 dBm (i.e. 36 dBm EIRP), the interference level at the WLAN =  $28 - 22 - 86 = -80$  dBm. Taking into account the backoff,  
11 3 dB, and the effect of the Mesh activity factor, an additional 13 dB, brings the average interference level, -97 dBm,  
12 far below receiver sensitivity values. Operation of a mesh device on the roof, while running an WLAN network inside  
13 is hence feasible, even in the same channel.  
14  
15  
16

17 In this scenario, to operate the WLAN at its highest modulation and coding rate (64 QAM, 3/4 coding) while the  
18 Mesh device is transmitting, would require the separation to be at least 20 meters. (instead of the 5 meters used). For  
19 (16 QAM, 1/2 coding), the separation would be 10 meters.  
20  
21

#### 22 A.2.4.2.1.2 'Across the street' analysis (2) 23 24

25 Another critical consideration is the analysis of illumination of indoor WLANs in adjacent buildings. This is due to  
26 the fact that despite the larger distance, normally only one isolating building layer (which may also be a window) is  
27 situated in-between, and the Mesh antenna gain increases with the angle from the vertical axis.  
28

29 It is assumed for this scenario that the street is 10 m wide, which gives an antenna gain of -15dBi and an outdoor dis-  
30 tance of  $\sqrt{125} = 11.2$  m. The structural isolation plus attenuation due to multipath/scattering is assumed to be 10 dB  
31 (window plus some indoor scattering). The total attenuation is then  $10 + 20 \cdot \log_{10}(4 \cdot \pi \cdot d \cdot f_0 / c) = 78$  dB. Taking into  
32 account the antenna gain, the backoff and the mesh activity factor of the mesh node reduces the average level at the  
33 WLAN to -78 dBm.  
34  
35

36 Of course, the numbers in the above analysis fluctuate by a number of dB's for individual deployments. The average  
37 structural attenuation was quoted to be 13.4 dB in [B46], but there may be variations in building height or terrain  
38 sloping which increase the antenna gain in the direction of the WLAN by a few dBs. Typically however, the above  
39 results are broadly applicable as conservative estimates to a wide range of deployment scenarios.  
40  
41

42 Power-control and DFS can assist in further reducing these interference levels. Note that the transmit probability of  
43 the WLAN device, (13 dB), has not been taken into consideration.  
44  
45

#### 46 A.2.4.2.2 Outdoor WLAN analysis 47 48

49 An argument often used against the use of FWA devices in the 5GHz bands is that it will interfere with outdoor  
50 deployments of WLAN devices. It is quite obvious that co-location of these two types of devices on a roof (or neigh-  
51 boring roofs) will cause severe interference when operating in the same channel. However, it should be realized that  
52 exactly the same issue exists with two WLAN APs on a roof (or neighboring roofs) are competing for the same chan-  
53 nel. (To be specific, this is mostly the case for HIPERLAN/2, which is schedule based. IEEE 802.11a uses CSMA/CD  
54 attempting to avoid this type of interference, which works well for low duty-cycles.) In both cases, the requirement  
55 for a DFS mechanism can gracefully resolves the problem.  
56  
57

58 In addition, outdoor WLAN deployments are predominantly used for hot-spot coverage and bridging, which implies  
59 the use of down-tilted antennas and oftentimes geographical isolation for hot-spot coverage and very directive anten-  
60 nas for bridging, each of which reduces the interference potential. In the cases where WLANs are currently used for  
61 access provisioning, IEEE 802.16 compliant systems will likely not be deployed or be used as more efficient substi-  
62 tutes.  
63  
64  
65

1 FWA deployments require broad coverage and hence reasonable frequency re-use numbers to maintain sufficient Sig-  
2 nal-to-Noise Ratio plus limited DFS flexibility to avoid local interference sources. The likelihood of roof-mounted  
3 WLAN devices not finding a sufficiently noise-free channel for proper operation are therefor rather small.  
4

#### 5 6 **A.2.4.2.3 Network analysis** 7

8 To illustrate the interference analysis further, an example typical scenario, consisting of a 4 node indoor WLAN net-  
9 work and a nearby 4 node Mesh network, is examined.  
10

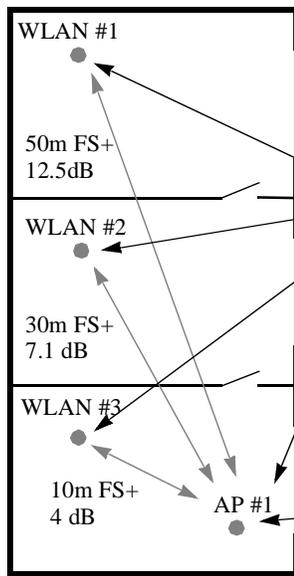

11 From Annex 2 of [B46], we extract that the typical indoor attenuation on top of free-space attenuation at 5 m is 4 dB  
12 for a mixture of line-of-sight through non-line-of-sight scenarios. The additional attenuation through 1 wall is 7.1 dB  
13 and the additional attenuation through 2 walls is 12.5 dB (the walls in these cases were breeze blocks and the rooms  
14 contained both wooden and metal furniture). The attenuation through a double-glazed window was found to be 7 dB.  
15  
16

17 In the case under study, a SU is assumed from each of these cases in a Small Office setting. The SU in the same room  
18 is assumed at 10 m, The SU in the adjacent room at 30 m and the SU behind two walls at 50 m.  
19  
20

21 The Small Office is assumed to be a single-floor building with a flat roof. The attenuation through the roof is 22 dB.  
22 19 dB is a typical indoor cross-floor attenuation according to Annex two of [B46], so this is probably a fairly pessi-  
23 mistic value. The Mesh #4 node is situated on the roof directly atop AP #1 and provides the 'Internet access' for the  
24 WLAN service within the building. This makes sense, as the cabling distance between the data gathering point, the  
25 AP, and the access service, Mesh #4 node, is shortest. The distance between AP #1 and Mesh #4 is assumed to be 5m.  
26  
27

28 The nearest neighboring node, Mesh #1, is 50 m away on an adjacent building. The building attenuation is 10 dB (a  
29 window plus indoor scattering, as in clause A.2.4.2.1.2. It is assumed that this building is lower than the building with  
30 the WLANs, resulting in an antenna gain of -10 dBi in the direction of the WLANs, rather than the -15 dBi specified  
31 in Table 2). Two other nodes are each 200m away as shown in Figure 5. All mesh nodes are on the roof and hence  
32 only have free-space (FS) attenuation to each other. Mesh #3 is assumed to have an additional 15 dB obstruction to  
33 the WLANs in the form of a building (basically the building on which Mesh #2 is located).  
34  
35  
36

37 Note that in the Path Losses in Figure 5, the antenna gain of the Mesh nodes (see Table 2) in the direction of the  
38 WLANs has been included.

mesh#4 - WLAN#3	12m FS + 52dB

Figure 5—Example network scenario

In Table 16, the ranges and corresponding total link attenuations, which are assumed to be symmetrical, are gathered. In general, it can be observed that only nodes that are really close or in line of sight through little attenuation (particularly windows) result in significant interference.

Table 16—Link attenuations and ranges

	Link attenuation / Range							
	Mesh #1	Mesh #2	Mesh #3	Mesh #4	AP #1	WLAN #1	WLAN #2	WLAN #3
Mesh #1	-----	200 m	400 m	50 m	50 m	60 m	60 m	60 m

In Table 17, the maximum power and EIRP values for each of the devices is shown. For the WLAN devices and their AP, values are chosen which reflect implementations as are currently available in the market.

**Table 17— Tx Power, conducted and EIRP (regulatory limited)**

	AP	WLAN	mesh
Tx Power (mW)	200	200	500
Antenna (dBi)	2	0	8
EIRP (dBm)	25	23	35

In Table 18, the resulting received signal strengths are shown assuming transmission with EIRP values as shown in Table 17. Note that especially between the mesh nodes, the Rx values are extremely high, which would automatically be reduced by the AGC. For simplicity of computation, this is however ignored. This table is not symmetric since different antenna gains at each end can affect the perceived signal level.

**Table 18—Received Signal Levels (dBm)**

	Mesh #1	Mesh #2	Mesh #3	Mesh #4	AP #1	WLAN #1	WLAN #2	WLAN #3
Mesh #1	-----	-54	-60	-42	-80	-83	-83	-83
Mesh #2	-54	-----	-54	-54	-97	-100	-100	-100
Mesh #3	-60	-54	-----	-61	-119	-121	-121	-121
Mesh #4	-42	-54	-61	-----	-84	-102	-98	-93
AP #1	-76	-93	-115	-80	-----	-72	-62	-50
WLAN #1	-79	-96	-117	-98	-72	-----	-112	-74
WLAN #2	-79	-96	-117	-94	-62	-112	-----	-87
WLAN #3	-79	-96	-117	-89	-50	-74	-87	-----

Table 19 below shows the results. The top row in each box shows the actual communication direction, the used modulation and the Noise threshold. The four next rows illustrate the effect of interference from each source (using maximum allowed EIRP). If the modulation differs from the top box, then switch to a more robust modulation scheme was mandatory to maintain 3% PER. The last column defines the interference margin. A positive value means the threshold has been exceeded and is shown in bold.

Table 19—Sustainable modulation during interference

WLAN#1 =>AP#1	3/4 QPSK	-90	WLAN#2 =>AP#1	2/3 64QAM	-95	WLAN#3 =>AP#1	3/4 64QAM	-95

mesh #1	<b>PER&gt;3%</b>	<b>1</b>	mesh #1	3/4 QPSK	-8	mesh #1	3/4 QPSK	-8
mesh #2	3/4 QPSK	-16	mesh #2	3/4 64QAM	-25	mesh #2	3/4 64QAM	-25
mesh #3	3/4 QPSK	-37	mesh #3	3/4 64QAM	-46	mesh #3	3/4 64QAM	-46
mesh #4	3/4 QPSK	-18	mesh #4	2/3 64QAM	-23	mesh #4	3/4 16QAM	-18

From Table 19, two observations can be generalized. The first is that in certain scenarios interference is unavoidable if DFS is not used. The second is that interference only occurs when nodes are really close (such as mesh #4) or have relatively good line of sight properties (such as mesh #1, which only has a window in-between and a reduced height antenna) to the WLAN network. The later generalization means that very few nodes in a mesh network will cause degradation of a WLAN network. Realizing that the interference excess is relatively low, and the mesh network further uses power-control to reduce the EIRP where possible, interference from a transmitting mesh device will be very limited. Combined with the activity factors for both devices (on average 13 dB each) and DFS mechanisms, the likelihood of interference becomes so small that it is easily handled with Automatic Request (ARQ) causing minimal degradation of performance.

#### A.2.4.2.4 Adjacent channel issues

A nice feature of the OFDM technology used in both WLANs and Mesh technology at 5GHz, is that the adjacent channel rejection is very high, at least 35 dB (compare clause 8.3.6.4.2.4.2). Since the interference levels between WLANs and Mesh devices are relatively low compared to this (see previous sections), it is reasonable to assume that adjacent channels using WLAN and Mesh technology will not cause any noticeable interference to each other. Therefore, this is not further considered here.

#### A.2.4.3 Interference to RTTT

1 In accordance with [B46], [B52], the cross-polarization is assumed to be 10-15 dB to the RSU and 6-10 dB to the  
 2 OBU (Table 20 uses the lower numbers).  
 3  
 4

5 **Table 20—Needed separation distance mesh to RSU and OBU**  
 6

Parameter	RSU		OBU	
$P_t$	6		6	dBW
$B_{Rx}$	10	5	10	MHz
$B_i$	22		22	MHz
$I_{Rx}=R_{x_{sens}}-C/I_{8PSK}$	-117		-90	dB
$L$	119.6	116.6	92.6	dBW
cross-polarization	10		6	dB
Antenna & feeder gain	8		8	dB
<b>Separation distance</b>	<b>553</b>	<b>394</b>	<b>53</b>	<b>m</b>

 20  
 21  
 22  
 23  
 24  
 25  
 26  
 27 It should be noted that in the above calculations, the duty-cycle of the Mesh devices, which significantly reduces the  
 28 interference scenario, has not been taken into consideration.  
 29

30 Especially for the RSU case, where the separation distance is fairly significant, it can be shown that the interference  
 31 to the Mesh device is significantly larger than the other way around. Since RTTT devices normally have a fairly high  
 32 duty-cycle, a close Mesh device would not be able to operate properly in this channel and would need to use the DFS  
 33 mechanisms to switch to another channel. Therefore, for RSUs, proper operation is virtually guaranteed by virtue of its  
 34 own interference potential.  
 35  
 36

#### 37 **A.2.4.4 Interference to Radar** 38 39

40 For radars, a somewhat similar situation exists as with RTTT RSUs. To show this, the interference distance from  
 41 radars into Mesh devices is derived, followed by the derivation of the interference distance from Mesh devices into  
 42 radars. As is shown below, the first is much larger than the second, necessitating the use of the Mesh's DFS algorithm  
 43 to switch to another channel to survive, eliminating the interference potential to the radar.

**Table 21—Minimum separation distance of radar to mesh**

Radar type	A	B	C	D	E	
Peak EIRP	98.6	26	60	93	97	dBW
Antenna gain	40	0	46	43	43	dBi
$P_t$	58.6	26	14	50	54	dBW
$BW_{\text{radar}}$	3	15	30	14	3	MHz
$I_{\text{mesh}} = R_{x_{\text{sens}}} - C/I_{\text{BPSK1/2}}$	-116					dBW
L	174.6	142.0	131.3	166.0	170.0	dB
gain + feeder loss	48	8	54	51	51	dB
propagation loss	222.6	150	185.3	217	221	dB
distance @ 5.5GHz	20693	137	497	11813	17630	km
radio horizon	51.4	346.6	51.4	51.4	51.4	km (see [B53])
<b>separation distance</b>	<b>51.4</b>	<b>137</b>	<b>51.4</b>	<b>51.4</b>	<b>51.4</b>	<b>km</b>

In Table 22, the thermal noise level has been assumed -204 dB/Hz, whereas the Rx noise factor is assumed 5 dB. The maximum I/N is -6 dB as specified by NATO (see [B46], [B53]).

**Table 22—Minimum separation distance of mesh to radar**

Radar type	A	B	C	D	E	
$P_t$ mesh	-2					dBW
$BW_{\text{radar}}$	3	15	30	14	3	MHz
Noise (dBW)	-134.2	-127.2	-124.2	-127.5	-134.2	dBW
On-tune rejection	-8.9	-1.9	0.0	-2.2	-8.9	dB (see [B46])
Max. Interference	-131.3	-131.3	-130.2	-131.3	-131.3	dBW
L	129.3					dB
gain + feeder loss	48	8	54	51	51	dB
propagation loss	177.3	145.3	191.6	188.3	188.3	dB
<b>distance @ 5.5GHz</b>	<b>220.1</b>	<b>79.4</b>	<b>916.3</b>	<b>662.7</b>	<b>662.0</b>	<b>km</b>

Comparing the result of Table 21 (line 10) and Table 22 (line 10), we see that in all cases, the separation distance is larger for the FWA system, forcing it effectively out of the channel used by the radar. In all cases, the separation distance is effectively limited by the radio horizon.

1 In the case of Radar type B, which is airborne, depending on the exact location of the radar, the gain+feeder loss will  
 2 reduce from +8 to -22 dB, significantly reducing the necessary separation distance. Since the angle of detection (if  
 3 any) is not known, this factor has not been used in the above tables. For the other types, the distance is limited by the  
 4 radio horizon, but in practice likely much lower due to obstructions and clutter.  
 5

6  
 7 From the above tables, similar conclusions to the WLAN analysis in [B46] can be drawn. Sharing with maritime  
 8 radars (which are not likely operating anywhere near residential areas) and S5.452 meteorological radars in band B  
 9 and radiolocation radars in both band B and C is feasible when an effective DFS mechanism is employed by the Mesh  
 10 system and the radar density isn't too high.  
 11
