Szczepanek, Andre — Texas Instruments

Comment Type **TR** *Comment Status* **A**

""The value of the pseudo-random bit shall be derived from a random or a pseudo-random source"".
Failing to specify the pseudo-random source for this bit will make compliance testing dificult - how can we determine that the bit is truly random or pseudo-random. If the bit was explicitly stated to be the result of a defined generator polynomial checking compliance would be straightforward

Suggested Remedy

Explicitly define the pseudo-random counter generator polynomial. The polynomials used in 48.2.4.2 may suffice. For simplicity the counter should increment once per DME page.

Response *Response Status* **C**

ACCEPT.

Will use polynomial in 48.2.4.2.

Cl **28E** *SC* **5.2** *P* **14** *L* **2** # **56**

Szczepanek, Andre — Texas Instruments

Comment Type **E** *Comment Status* **A**

I do not understand what this paragraph means, as currently worded.
In particular I do not understand the relevance of ""transmitter operating at less than its highest supported baud rate"" to the receiver. The receiver must be capable of receiving DME signals sent with any of the electrical specifications of 802,3ap (1000BASE-KX,10GBASE-KX4 or 10GBASE-KR).
My suggested remedy is what I think it should be saying …

Suggested Remedy

""To be able to detect the DMEs, the receiver should have the capability to receive DME signals sent with the electrical specifications of any IEEE802.3 backplane Ethernet PHY (1000BASE-KX,10GBASE-KX4 or 10GBASE-KR).""

It isn't clear why this register is a backplane Ethernet register. The items here seem all to apply equally to auto-negotiation as defined in Clause 28 and Annex 28E.
Also the formating is different than most register definitions where each bit or field ndefinition has its own subclause.

Suggested Remedy

Delete Backplane Ethernet and apply this register across autonegotiation if my comment is correct. In any case, make the format consistant by putting in sub clauses for the bit/field definitions.

Response *Response Status* **C**

ACCEPT IN PRINCIPLE.

Thaler, Pat — Agilent Technologies

Comment Type **TR** *Comment Status* **A**

This register should have separate bits to indicate abilities for Backplane Ethernet (or Clause 28E) auto-negotiation or FLP autonegotiation (or Clause 28).
For FLP autonegotiation, there should be an extended next page ability bit unless there is a statement requiring all devices that support this clause to provide auto-negotiation ability. The extended next page ability bit part of the comment has been submitted to 10GBASE-T which should handle it and is only submitted here for information

Suggested Remedy

See comment.

Response *Response Status* **C**

ACCEPT IN PRINCIPLE.

Add the following
This only applies to a device that will support extended autonegotiation pages.

Cl **45** *SC* **45.2.7.2.3** *P* **59** *L* **1** # **86**

Thaler, Pat — Agilent Technologies

Comment Type **E** *Comment Status* **A**

The format of subclauses for extended page values should be harmonized with the descriptions of extended next pages in 10GBASE-T. For example, the lower numbered register, 7.9 should be at the top of the table followed by 7.10 and 7.11.

Suggested Remedy

Correct format.

Response *Response Status* **C**

ACCEPT.

Cl **45** *SC* **45.2.7.2.3** *P* **59** *L* **1** # **100**

Thaler, Pat — Agilent Technologies

Comment Type **TR** *Comment Status* **A**

For all multi-register values, something similar to the handling of multi-register counters needs to be added. Otherwise inconsistant values may be retrieved or sent. When the first (e.g. 7.9) register is read, the other register values should be latched.
For the multi-register values that are writeable, the value should only be transferred to the state machine when the first register is written. It might seem more logical to do this when the third register is written, but there are times when only the first register needs to be updated so it is more efficient to have the write to this register trigger action.

Suggested Remedy

Put in text similar to that for counter values that says that the value of the three registers is latched when the first register is read and reads of the second and third registers return the latched value rather than the current value.
For writeable registers, indicate that the value is only used by the state machine when the first register is written. For the base page, the value is transferred to mr_adv_ability when the first word is written. For next pages, the value is transferred to mr_np_tx and mr_next_page_loaded is set when the first word is written. Therefore, when writting all three registers the second and third registers should be written before the first register.

Brink, Robert — Agere Systems

Comment Type **T** *Comment Status* **D**

1) The Signal Detect electrical specifications were derived from CX4, a cable standard.
2) Analog Signal detectors are tricky to design robustly across Process, Voltage, and Temperature.
3) The Signal_Detect is not the ultimate authority on the quality of the data but rather it signals that there is sufficient energy at the receiver inputs.
I would like to propose modifying the SIGNAL_DETECT section to make it less timing and level critical. Specifically, I propose a longer time constant for detecting valid signal levels and a higher threshold for SIGNAL_DETECT = FAIL to account for the additional crosstalk that is expected in a backplane v.s. a cabled system.

Suggested Remedy

reword this section to read:
SIGNAL_DETECT is a global indicator of the presence of electrical signals on all four lanes. The PMD receiver is not required to verify whether a compliant 10GBASE-KX4 signal is being received, however, it shall assert SIGNAL_DETECT=OK within 100us after the absolute differential peak-to-peak input voltage on each of the four lanes at the MDI has exceeded 175mV for a period of at least 100UI (10 code group ordered sets).
The PMD shall not assert SIGNAL_DETECT = FAIL until at least 250usecs after any event causing the assertion or reassertion of SIGNAL_DETECT = OK. The PMD shall have asserted SIGNAL_DETECT = FAIL when the absolute differential peak-to-peak input voltage on any of the four lanes at the MDI has dropped below 75mV and has remained below 75mV for longer than 500us.

Comment Type **TR** *Comment Status* **A**

Reference to Annex 48A test patterns is not appropriate for 10GBASE-KR (not 8B10B encoded). Annex 48B may also not be directly applicable.

Suggested Remedy

Identify alternate test pattern, using the facilities of 49.2.8. Review Annex 48B methodology to identify what modifications are necessary to yield a transmit jitter test for 10GBASE-KR.

Response *Response Status* **C**

ACCEPT IN PRINCIPLE.
Change text to read
Transmit jitter is defined with respect to a test procedure resulting in a BER bathtub curve such as that described in Annex 48B.1. For the purpose of jitter measurement, the effect of a single-pole high pass filter with a 3 dB point at Fbaud/1667 is applied to the jitter. The data pattern for jitter measurements shall be the patterns defined in Annex's 49.2.6 and 49.2.8. Channels are active in both directions, and opposite ends of the link use asynchronous clocks. Crossing times are defined with respect to the mid-point (0 V) of the AC-coupled differential signal.
