This document is presented as a comparison document, compared to http://ieee802.org/3/bm/public/mmfadhoc/meetings/jun12 14/8023-95-TxVEC CMP.pdf

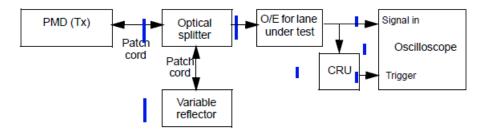

95.8.5 Transmitter vertical eye closure (TxVEC)

TxVEC of each lane shall be within the limits given in Table 95–6 if measured using the methods specified in 95.8.5.1 and 95.8.5.2.

TxVEC is a measure of each optical transmitter's vertical eye closure; it is based upon vertical histogram data from an eye diagram measured through an optical to electrical converter (O/E) with a bandwidth equivalent to a combined reference receiver and worst case optical channel. Table 95–10 specifies the test patterns to be used for measurement of TxVEC.

95.8.5.1 TxVEC conformance test set-up

A block diagram for the TxVEC conformance test is shown in Figure 95–3. Other measurement implementations may be used with suitable calibration.

Text from Figure 95–3 repeated for editing purposes below

PMD (Tx) Patch cord Optical splitter Patch cord Variable reflector O/E for lane under test Oscilloscope Signal in Trigger CRU

Figure 95-3—TxVEC conformance test block diagram

Each optical lane is tested individually with all other lanes in operation. The optical splitter and variable reflector are adjusted so that each transmitter is tested with an optical return loss of 12 dB.

The combination of the O/E and the oscilloscope used to measure the optical waveform has a fourth-order Bessel-Thomson filter response with a bandwidth of 12.6 GHz. Compensation may be made for any deviation from an ideal fourth-order Bessel-Thomson response.

The clock recovery unit (CRU) has a corner frequency of 10 MHz and a slope of 20 dB/decade.

95.8.5.2 TxVEC measurement method

The oscilloscope is set up to accumulate samples of the optical eye diagram of the transmitter under test, as illustrated in Figure 95–4.

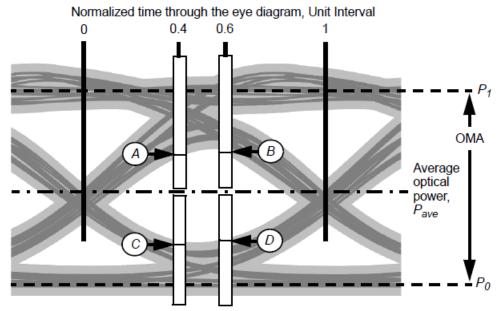

OMA is measured according to 95.8.4. The power of the optical zeros (P0) and the power of the optical ones (P1) are recorded. Also the standard deviation of the noise of the oscilloscope, *S*, is found with no input optical signal and the same settings as used to capture the histograms described below.

The average optical power (P_{ave}) and the crossing points of the eye diagram, and the four vertical histograms used to calculate TxVEC, are measured using Pattern 3 or Pattern 5.

The 0 UI and 1 UI crossing points are determined by the time average of the eye diagram crossing points, as measured at P_{ave} , as illustrated in Figure 95–4.

Four vertical histograms are measured through the eye diagram, centered at 0.4 UI and 0.6 UI, and above and below P_{ave} , as illustrated in Figure 95–4.

Each histogram window has a width of 0.04 UI. Each histogram window has an inner height boundary which is set close to P_{ave} (so that no further samples would be captured by moving it closer to P_{ave}), and an outer height boundary which is set beyond the outer-most samples of the eye diagram, so that no further samples would be captured by increasing the outer boundary of the histogram. Starting from the boundary of the histogram closest to the average optical power level, the optical power at which the cumulative distribution of each histogram equals the 0.005th percentile of the total number of samples for each histogram is recorded (these are the powers A, B, C, and D illustrated in Figure 95–4).

In Figure 95–4, delete the round labels and arrows A, B, C D. The values of P1 and P2 are not used in the calculation; they could be deleted if desired

Figure 95–4—Illustration of the TxVEC measurement

The distributions of the two histograms on the left are each multiplied by Q functions, which represent an estimate of the probability of errors caused by each part of the distribution for the greatest tolerable noise that could be added by an optical channel and a receiver. The resulting distributions are integrated and each integral is divided by the integral of the distribution it was derived from, giving two BER probabilities. The Q function uses a standard deviation σ_L chosen so that the average of these two BER probabilities is 5×10^{-5} . Similarly, for the distributions of the two histograms on the right, a standard deviation σ_R is found.

Q(x) is the area under a Normal curve for values larger than x (the tail probability, related to the "complementary error function"):

$$Q(x) = \int_{x}^{\infty} \exp(-z^{2}/2) / \sqrt{2\pi} dz$$
 (95–1)

where x is $(y - P_{ave})/\sigma_G$ or $(P_{ave} - y)/\sigma_G$ as in Equation (95-2).

This procedure finds a value of σ_G such that Equation (95-2): is satisfied:

$$(\int fu(y) \ Q((y - P_{ave})/\sigma_G) dy \ / \int fu(y) \ dy + \int fl(y) \ Q((P_{ave} - y)/\sigma_G) dy \ / \int fl(y) \ dy) \ / \ 2 = 5 \times 10^{-5}$$
(95–2)

where fu and fl are the upper and lower distributions and σ_G is the left or right standard deviation, σ_L or σ_R .

The lesser of σ_L and σ_R is N.

The noise that could be added by a receiver, R, is given by

$$R = \sqrt{(N^2 + S^2 - M^2)} \tag{95-3}$$

TxVEC is defined as the largest of the four quantities given by Equation (95-1) to Equation (95-4):

$$TxVEC(A) = 10\log_{10}(\frac{(P1 - Pave)}{(A - Pave)})$$
 (95.1)

$$TxVEC(B) = 10\log_{10}((P1 - Pave) / (B - Pave))$$
 (95-2)

$$TxVEC(C) = 10\log_{10}(\frac{(Pave - P0)}{(Pave - C)})$$
 (95-3)

$$TxVEC(D) = 10\log_{10}((Pave - P0) / (Pave - D))$$
 (95-4)

where *M* is a term to account for the mode partition noise and modal noise that could be added by the optical channel, and *S* is the standard deviation of the noise of the oscilloscope.

$$M = \sqrt{((0.02570MA)^2 + (0.01P_{ov})^2)}$$
 (95-4)

where

 P_{ave} is the average optical power of the eye diagram, and

P0, P1 OMA are is the optical modulation amplitude powers of 0 and 1 as defined for OMA in 95.8.4

A, B, C, D are the 0.005th percentile optical power levels of the four vertical histograms described in 95.8.5.2.

TxVEC is given by:

$$TxVEC = 10\log_{10}(OMA / (2\times 3.8906R))$$
 (95-5)

The factor 3.8906 is chosen for consistency with the BER limit of 5×10^{-5} given in 95.1.1.

or The factor 3.8906 is chosen because Q(3.8906) is 5×10^{-5} which is the BER limit given in 95.1.1.

or NOTE—Q(3.8906) is 5×10^{-5} which is the BER limit given in 95.1.1.

The method described in 95.8.5.2 is the reference measurement method. Other (equivalent) measurement methods may be used with suitable calibration.
