“Laser Control” into Discovery Processing State Diagram

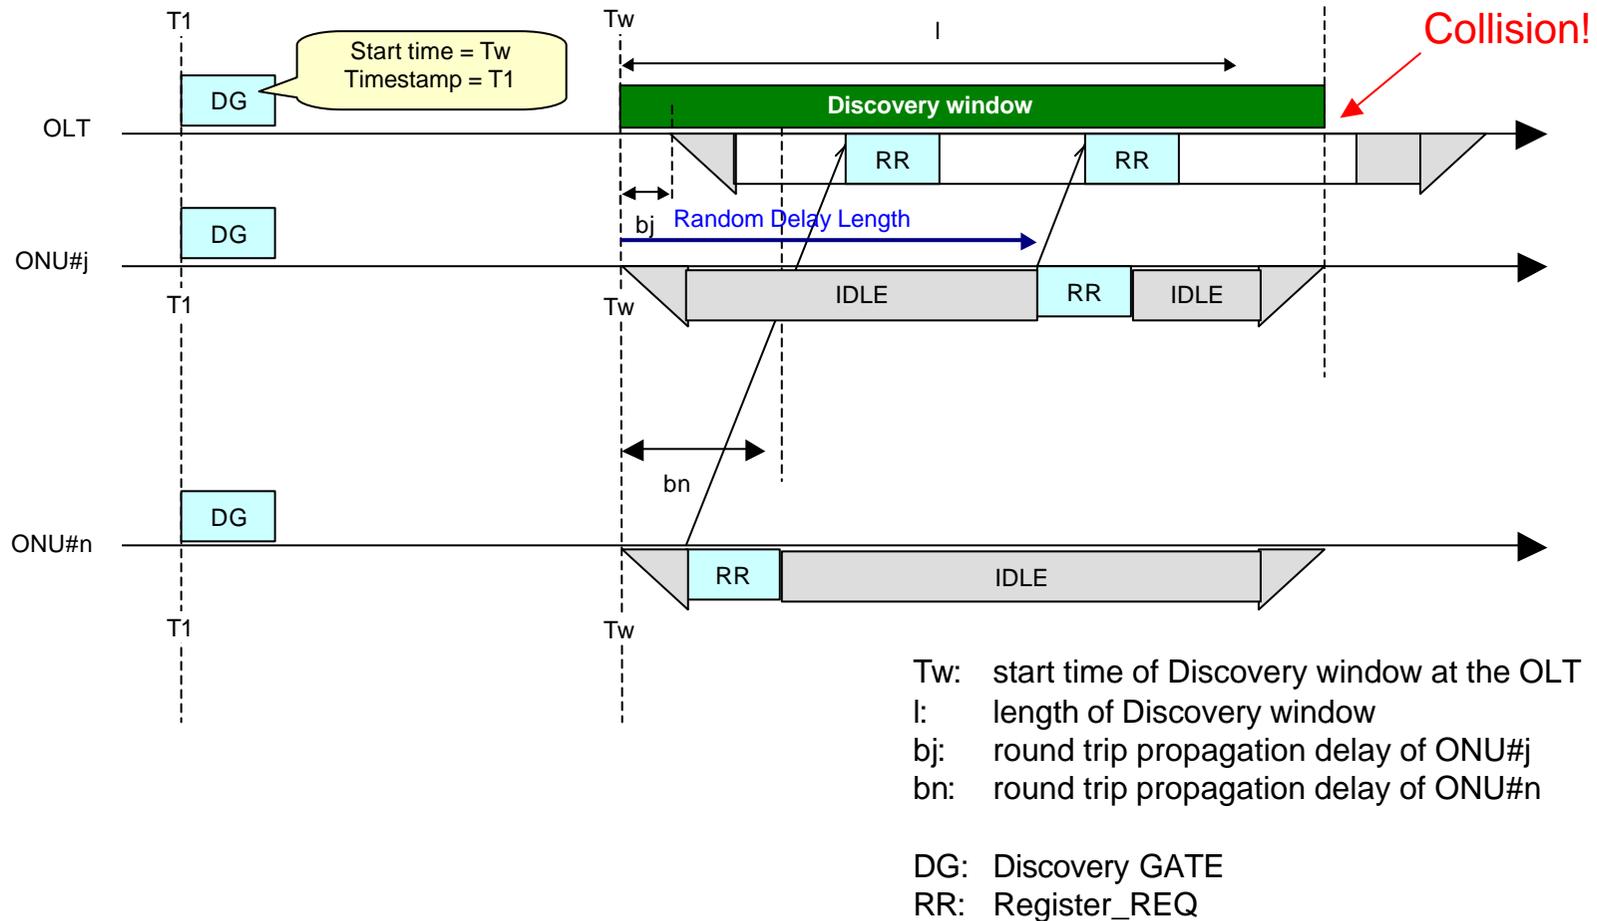

Yasuo Ogura NTT  
Yukihiro Fujimoto NTT

# Current state diagram : No relationship between Gate and Report

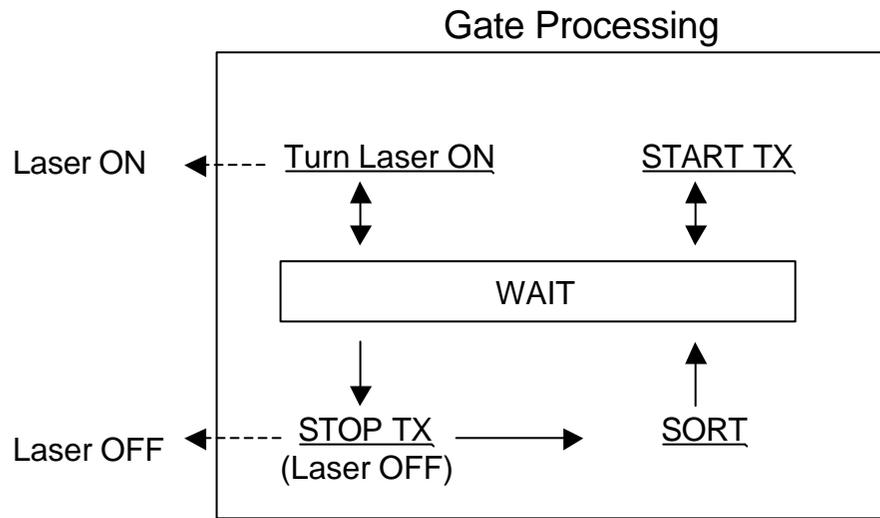

There is no relationship between "Gate Processing" and "Report Processing", so that Laser will be ON/OFF independent to send Register\_REQ or not.

## Problem : Collision in the Discovery window

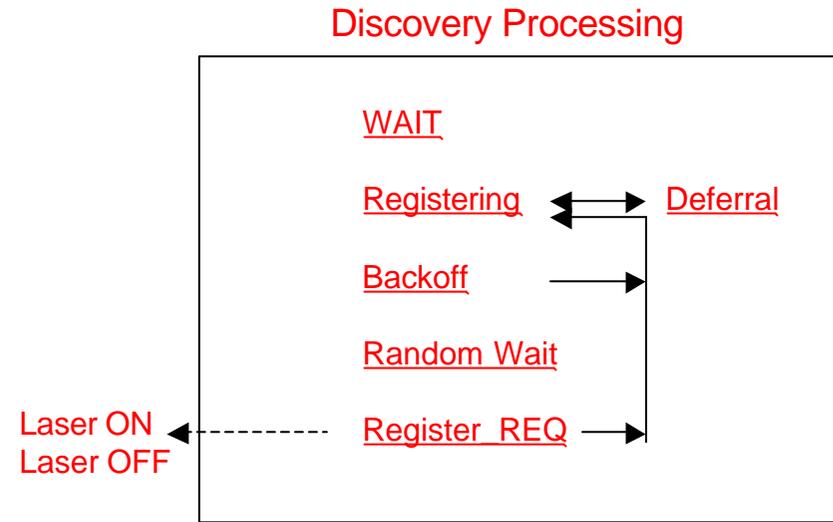

When ONU#j and ONU#n turn Laser ON, collision will happen in the Discovery window.  
 It seems difficult to process AutoDiscovery successfully when multiple ONUs are power ON.

# Proposed state diagram : Discovery Processing controls Laser ON/OFF

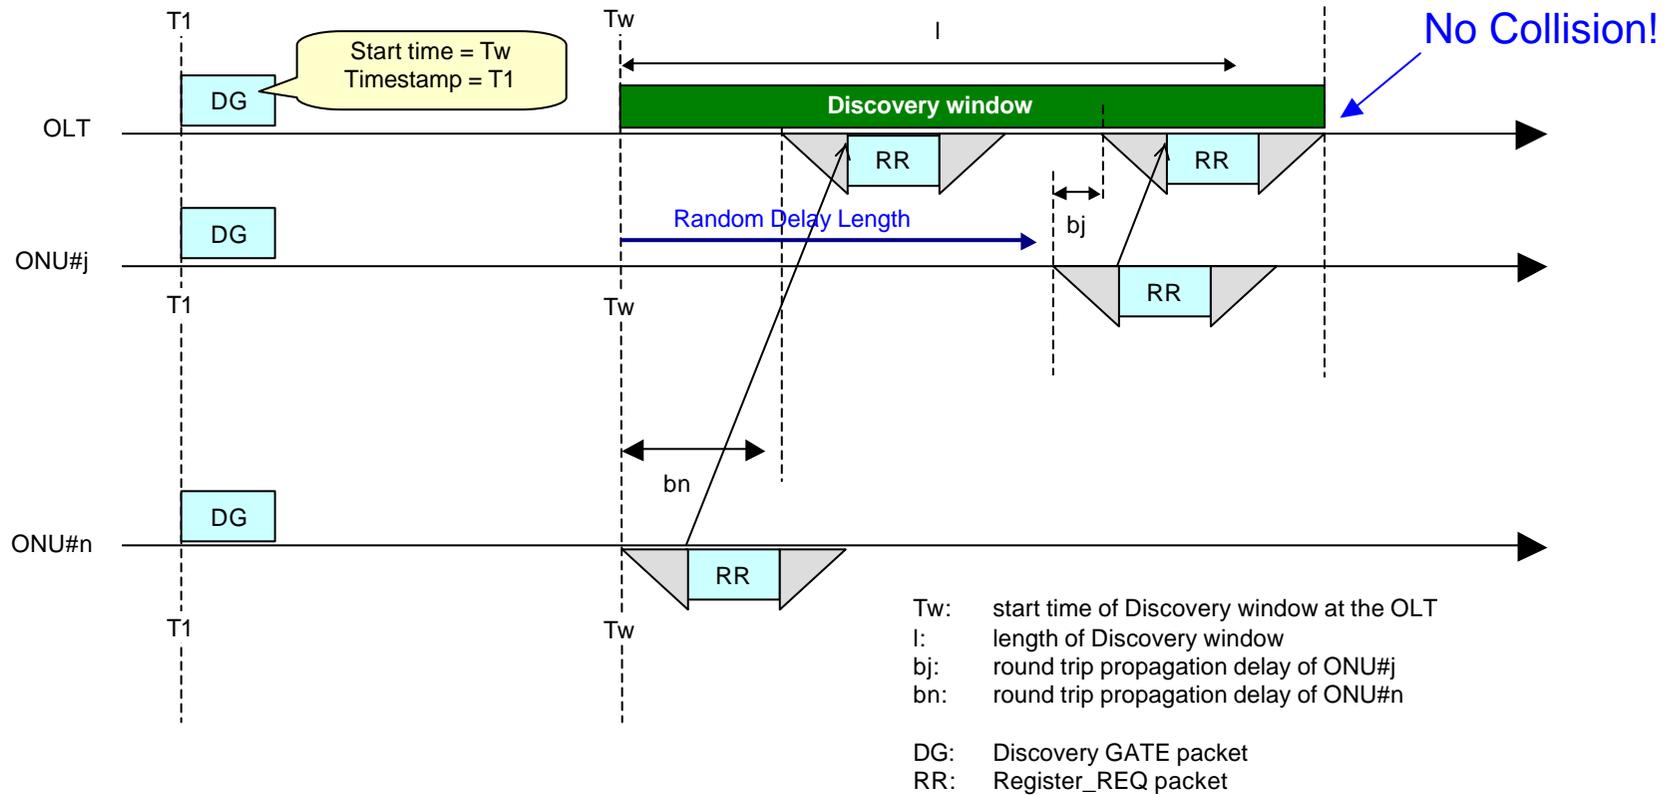

Gate Processing control "Laser ON/OFF" for Normal Gate.

Report Processing sends REGISTER\_REQ MPCPDU and controls Laser ON/OFF for Register.

Turn laser ON while ONU is sending a Register\_REQ only.

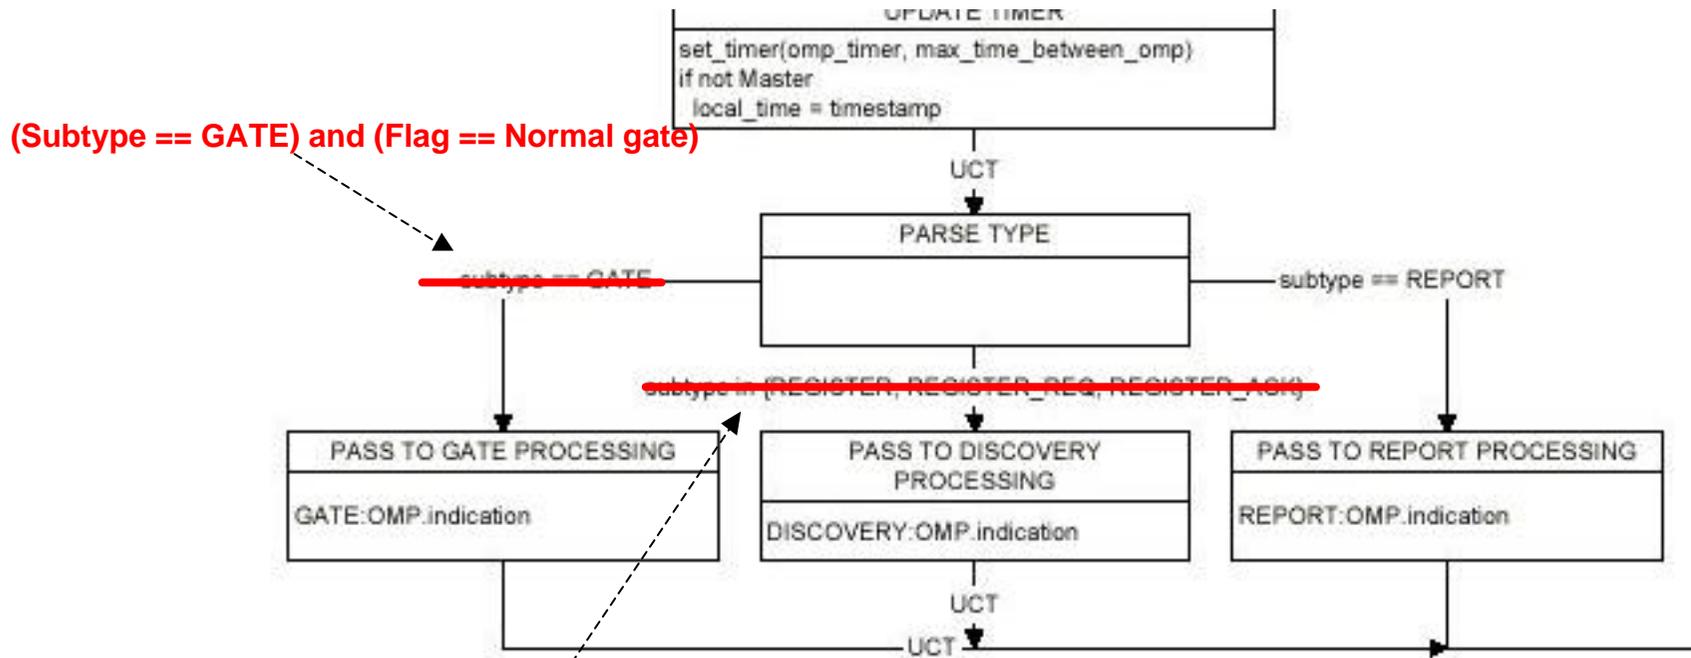

## Solution:Laser ON/OFF during Register\_REQ

Turn laser ON while ONU is sending a Register\_REQ only.  
 It seems easy that OLT receive multiple Register\_REQ in a single  
 Discovery Window.

# Proposal: OMP Parser/Multiplexer RX State Diagram

P.126 56.3.3.1.6 State Diagram

(Subtype == GATE) and (Flag == Normal gate)

# Proposal : Add variables

---

## 56.3.4.1.2 Variables

.....  
.....  
.....

### **LaserControl**

This variable is used to control the transmit path. It is set to true when the transmit path is enabled, and is set to false when the transmit path is being shut down. LaserControl is always on for the OLT, except when disabled, and changes its value according to the state of the Gate Processing sublayer.

TYPE:           on/off  
DEFAULT VALUE:  off for ONU  
                 on for OLT

### **TXAllow**

This variable is used to control PDU forwarding in the transmit path. It is set to true when the transmit path is enabled, and is set to false when the transmit path is being shut down. TXAllow is always true for the OLT, and changes its value according to the state of the Gate Processing sublayer.

TYPE:           boolean  
DEFAULT VALUE:  false for ONU  
                 true for OLT

### **IDLE\_time**

This variable holds the time required to stabilize the receiver at the OLT. It counts in time\_quanta units from the point where transmission output is stable to the point where it is decodable.

This value is set following registration, as it is broadcast by the OLT.

TYPE:           32 bit unsigned  
DEFAULT VALUE:  00-00-00-10 (256 nano seconds)

## Proposal : Add Constants and Timers

---

### 56.3.4.1.1      Constants

.....  
.....  
.....

**register\_req\_length**

This constants is used for setting the grant\_window timer. It represent the length of a REGISTER\_REQ MPCPDU and a preamble.

TYPE: 32 bit unsigned

DEFAULT VALUE: 00-00-00-24( 64+8 bytes )

### 56.3.4.1.4      Timers

.....  
.....

**IDLE\_timer**

This timer is used to wait for the event signaling the end of the period where no PDUs are allowed transmission inside the grant window. This period, where only IDLE symbol-pairs are transmitted is used to allow clock synchronization acquisition for the receiving entity.

**VALUE:**

**grant\_window**

This timer is used to wait for the event signalling the end of a grant window.

**VALUE:**
