

**Protocol Adaptation Layer (PAL)
for IEEE 1394 over IEEE 802.15.3
("wireless 1394")**

**Peter Johansson
Congruent Software, Inc.
IEEE 802 Tutorial
Portland, OR
July 13, 2004**

What is a PAL?

- A “glue layer” on top of a lower level

- Hides low-level details of underlying layer
- Mimics high-level behavior of target protocol
- For example, IP1394 is a PAL that permits Internet protocol to be carried by IEEE 1394

What use is a PAL?

- Leverages applications already developed

- Applications developed for IEEE 1394 expect:
 - Read, write and lock transactions
 - Infrastructure CSRs and configuration ROM
 - Asynchronous and isochronous streams

Wireless products enabled

- Firmware developed for (wired) IEEE 1394 products can migrate to wireless domain
- Minimize reengineering between wired and wireless domains

1394 PAL ground rules

- **Shall support IEEE 1394 TRAN layer functions**
 - Read, write and lock
- **Shall support isochrony and streaming data**
- **Shall coexist with other users of the underlying IEEE 802.15.3 transport**
- **Should behave “like” IEEE 1394**
- **Should conceal differences between IEEE 1394 and IEEE 802.15.3 physical and MAC layers**

Connect wireless to wired?

- 1394 PAL for IEEE 802.15.3 permits wireless devices to talk to each other

- Not always interesting unless wireless devices can also talk to (wired) IEEE 1394 devices

Wired to wireless *via* bridges

- IEEE P1394.1 bridge isolates physical and link (MAC) layer differences in each domain from the other

- IEEE P1394.1 preserves TRAN layer similarities
 - Transaction routes configured autonomously
 - Explicit isochronous stream setup / tear down

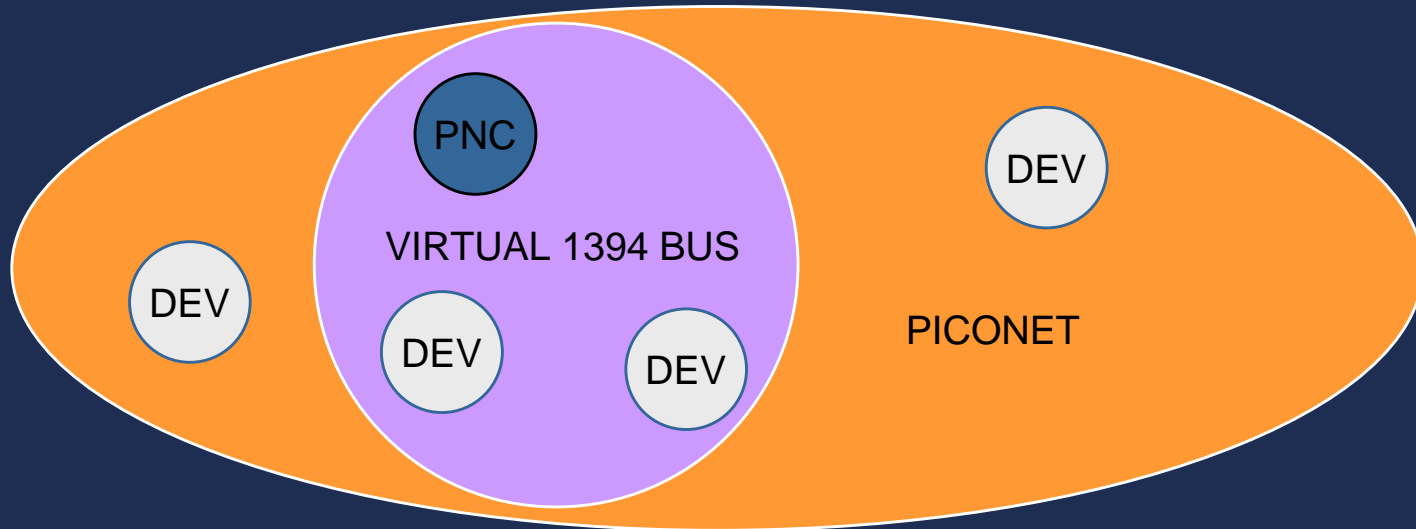

1394 TA project scope

Develop a document that specifies methods to *a)* mimic IEEE 1394 infrastructure (transactions, isochrony, stream data, configuration ROM and CSR architecture) using the facilities of IEEE 802.15.3 and *b)* implement IEEE P1394.1 bridge behaviors in the same domain. The methods are to be compatible with the simultaneous use of IEEE 802.15.3 by other protocols, *e.g.*, Internet protocol.

Summary of PAL features

- Virtual bus management
- IEEE 1394 packet encapsulation
- Split transaction time-out
- Cycle time synchronization
- Isochronous streams
- Isochronous connection management
- Control and status registers
- Configuration ROM

Virtual 1394 bus within a piconet

- **Wireless 1394 coordinator co-located with PNC**
 - Assigns 6-bit virtual IDs to wireless 1394 DEVs
 - Distributes synchronized cycle time

Bringing a new device home

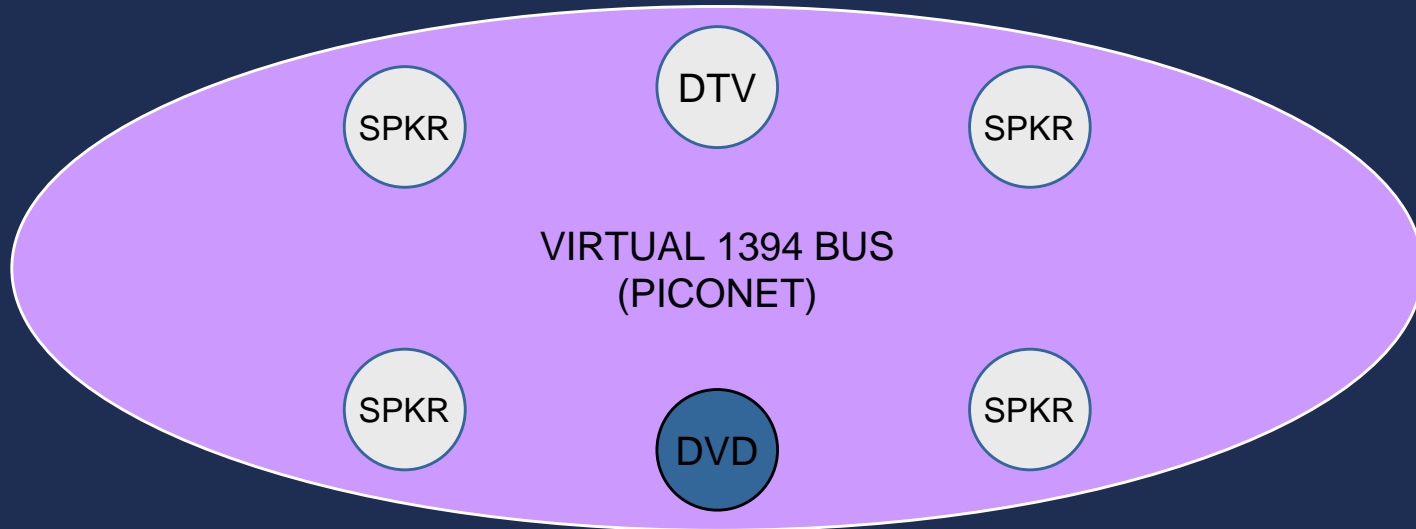

- **New, out-of-box device doesn't know it should associate with your piconet**
- **Possible metrics might choose incorrectly**
 - Radio signal from your neighbor's PNC might be stronger than your PNC's signal

Introducing a device to the right piconet

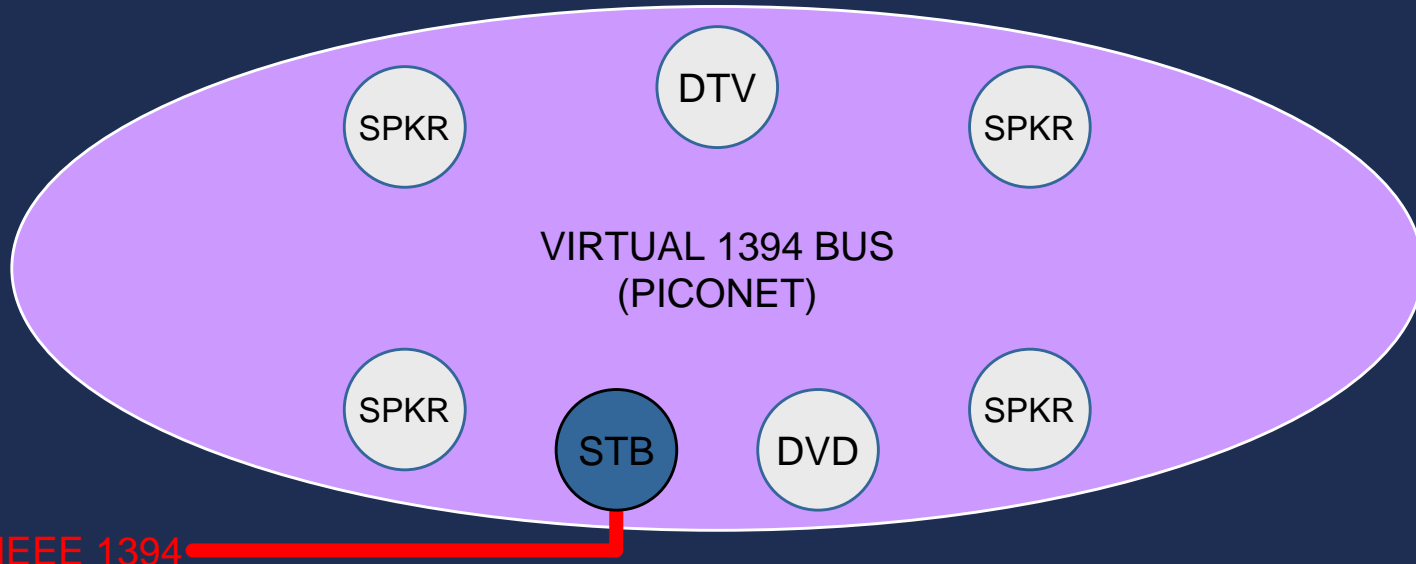

- New device flashes amber LED (disconnected)
- User first presses HANDSHAKE button on the PNC, next the new device's HANDSHAKE button
- Wireless 1394 coordinator admits only the one device whose HANDSHAKE button was pressed

Factory-configured components

- **DVD player is both PNC and wireless 1394 coordinator**
 - Access Control List (ACL) factory-initialized with MAC-64 IDs of wireless DTV and speakers
 - DTV and speakers automatically connect to virtual 1394 bus coordinated by the DVD player

New wireless 1394 coordinator

- Set DVD player's COORDINATOR switch off and STB's COORDINATOR switch on
- Introduce DVD player to STB (*via* HANDSHAKE)
- DVD transfers its ACL to the STB (DTV and speakers automatically connect to virtual 1394 bus coordinated by the STB)

IEEE 1394 packet encapsulation

- **Protocol ID identifies format that follows**
 - Used only with 802.15.3 stream index zero
- **1394 SDU analogous to IEEE 1394 packet**
 - Multiple 1394 SDUs permitted in a single 802.15.3 MSDU (isochronous data)

Protocol ID for IEEE 1394 PAL

- The 3-octet LLC header indicates that a SNAP header follows
- The 5-octet SNAP header consists of an OUI (*company_ID*) and a Protocol ID
 - 00 A02D₁₆ is 1394 Trade Association OUI
 - 201₁₆ specifies IEEE 1394 over IEEE 802.15.3

PAL header for 1394 SDU

tcodes-dependent	expiration_time		
destination_ID	tcodes-dependent	tcodes	tcodes-dependent
tcodes-dependent			

- Transaction code (*tcodes*) determines format

0, 1, 4, 5, 9 Request

2, 6, 7, B₁₆ Response

A₁₆ Stream (asynchronous or isochronous)

E₁₆ PAL control

PAL header for requests

	expiration_time			
destination_ID	tl		tcode	pri
source_ID				
destination_offset				
data_length	extended_tcode			
data (optional)				

- Data payload never present for read requests
- For write and lock requests, data payload present only if *data_length* is nonzero

PAL header for responses

	expiration_time			
destination_ID	tl		tcode	pri
source_ID	rcode		ext_rcode	
proxy_ID				
data_length	extended_tcode			
data (optional)				

- Data payload never present for write responses
- For read and lock responses, data payload present only if *data_length* is nonzero

PAL header for stream data

- **Nonzero *isochronous* bit specifies isochronous stream**
 - Data indicated to application at *cycle_time*
 - Permits multiple isochronous packets in a single 802.15.3 MSDU
- **Data payload present only if *data_length* is nonzero**

PAL control header

signature	expiration_time		
destination_ID	result	tcode	function
data_length	timeout		
data (optional)			

- **Used for control messages exchanged by PALs**
 - Virtual bus management
 - Isochronous connection management
- **Data payload present only if *data_length* is nonzero**

Split transaction time-out

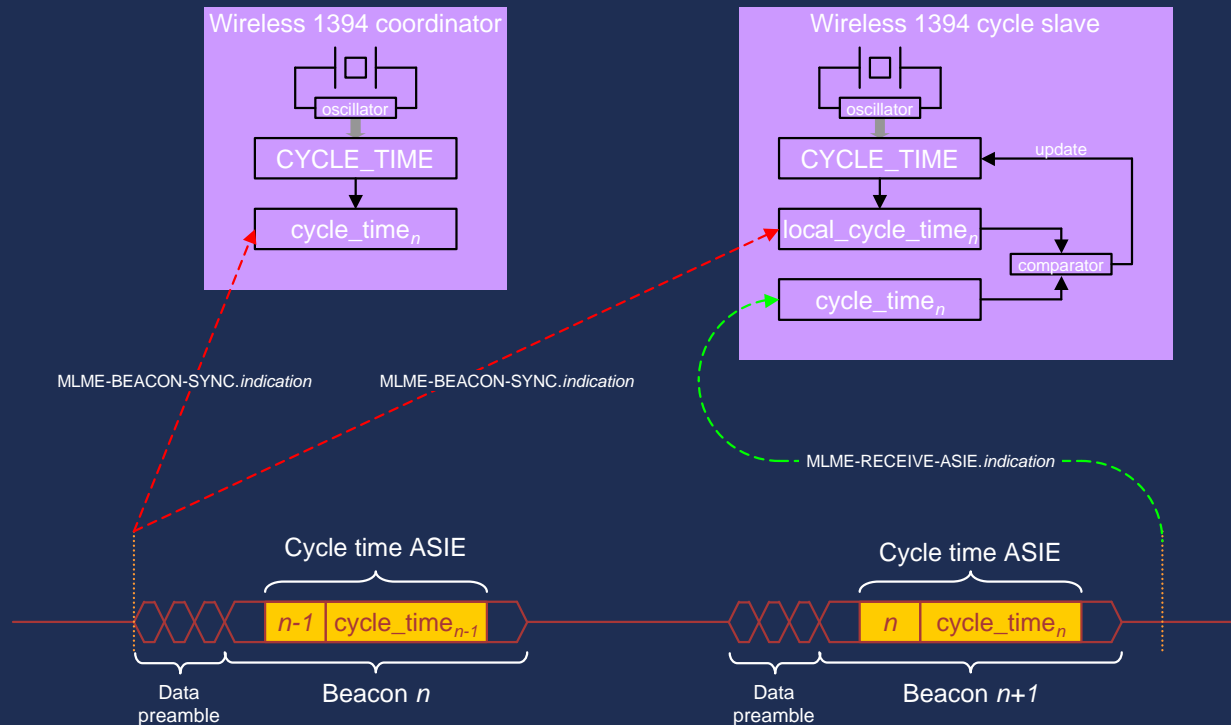

- **All wireless 1394 transactions are split**
 - Request subaction in one MSDU, response subaction in different MSDU
- **Difficult to control how much time the 802.15.3 MAC will use to transmit or retry an MSDU**
- **Split time-out controlled by *expiration_time***
 - Transmitting PAL calculates *expiration_time* for requests by adding SPLIT_TIMEOUT to cycle time
 - Receiving PAL discards requests and responses if *expiration_time* is earlier than cycle time

Cycle time broadcast in beacon

element_ID (6)
length
OUI (00 A02D ₁₆)
beacon_number
previous_bus_time
previous_cycle_time

- Each beacon contains an Application-Specific Information Element (ASIE) with master cycle time
- ASIE serves additional purposes:
 - Identifies presence of wireless 1394 coordinator
 - Supports HANDSHAKE mode for DEV introduction

Cycle time synchronization

- Upon *MLME-BEACON-SYNC.indication*, all wireless 1394 devices simultaneously sample CYCLE_TIME
- Wireless 1394 coordinator transmits its sample in the next beacon

Isochronous aggregation by transmitting PAL

- AV application informs PAL of optimal averaging window size for isochronous stream
- PAL accumulates at least this much data before encapsulating multiple 1394 SDUs in a single MSDU

Isochronous replay by receiving PAL

- Aggregated isochronous payload (2444 octets) requires approximately 200 μ s to transmit
 - Assume 100 mbps UWB PHY
- Earliest possible MSDU receipt for cycle 11
 - No allowance for retries
- End-to-end latency of 1.25 ms for this example

Isochronous connection issues

- Talker requests channel time from PNC
- Talker transmits on assigned stream index
- Listener receives from same stream index
- How does controller manage this?

Wireless input and output plugs

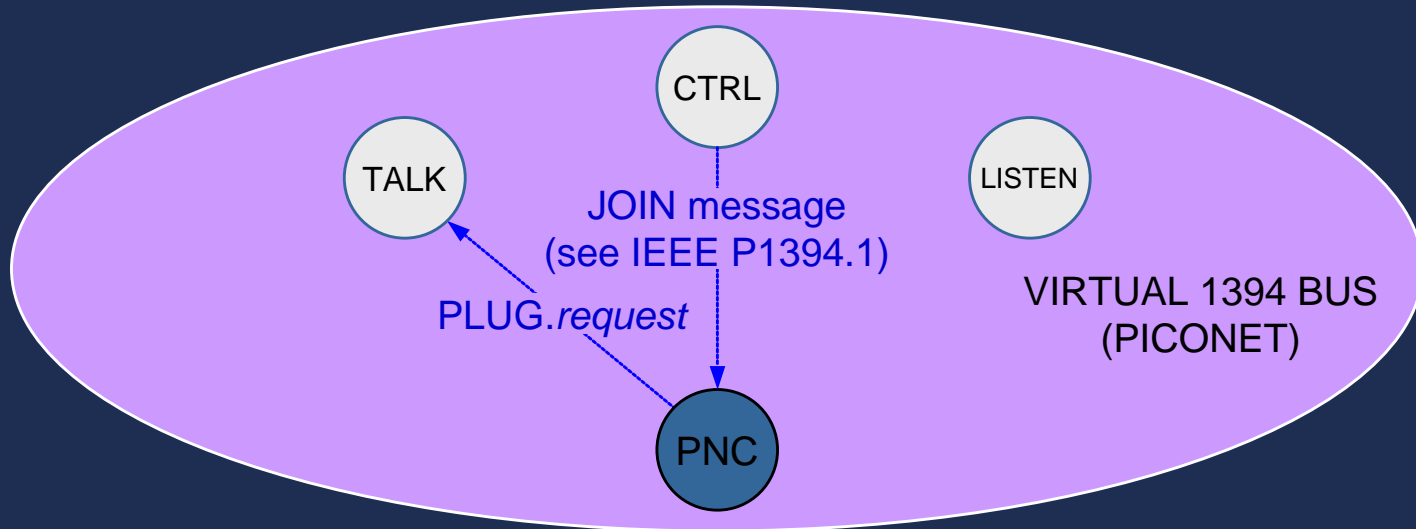

- Patterned after IEC-61883 iPCR and oPCR—but different
- Internal PAL data structure (not exposed as a CSR)
 - 802.15.3 stream index
 - Connections
 - Maximum and average data payload
 - Latency
 - Averaging window
- Correlate stream index with device's internal destination or source for isochronous data

Plug management SDU

signature		expiration_time		
destination_ID		result	rcode	function
data_length (12)		timeout		
d	plug	stream_index		listener_ID
max_payload		average_payload		
window		latency		

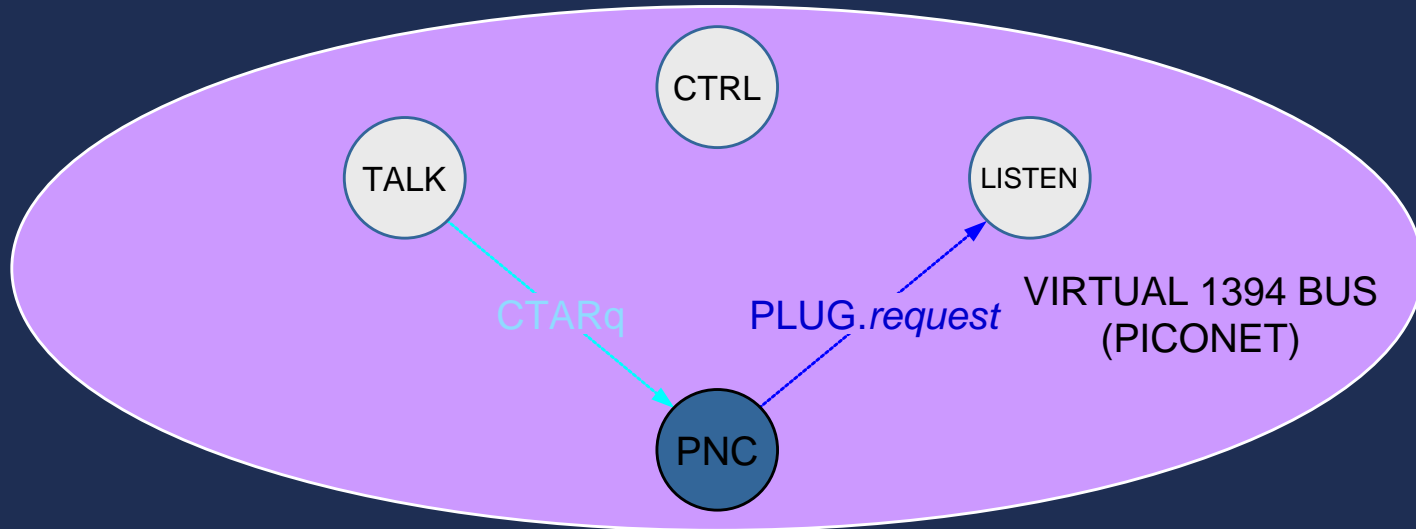

- Supports two functions
 - PLUG and UNPLUG
- Recipient may reject function if *latency* too great

Connection setup: JOIN message

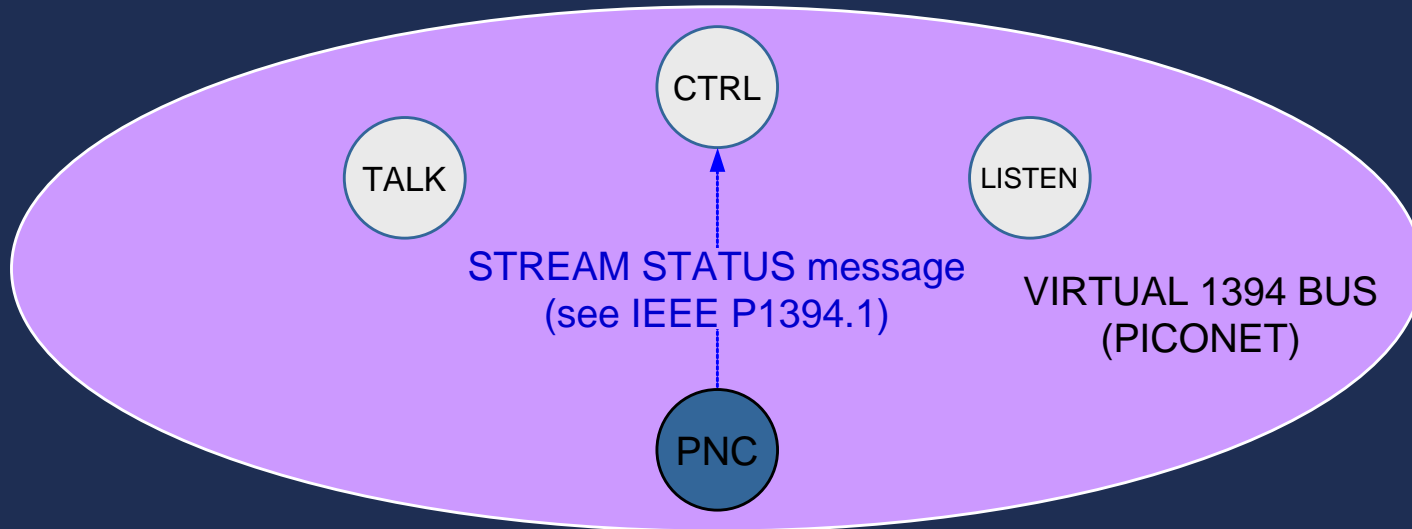

- **Controller transmits JOIN message to wireless 1394 coordinator at PNC**
 - Average payload, averaging window and latency
- **Wireless 1394 coordinator transmits PLUG request to talker**
 - Remembers JOIN information to monitor stream

Channel time allocation by talker

- **Talker requests channel time from PNC**
 - If channel time is available, PNC confirms request and assigns a stream index to identify the stream
- **Talker confirms PLUG request and informs wireless 1394 coordinator which stream index will be used**
- **Coordinator sends PLUG request to listener**

Connection established: STREAM STATUS message

- After receiving PLUG confirmation from listener, wireless 1394 coordinator returns STREAM STATUS message to controller
 - Channel time allocated by PNC
 - Both talker's and listener's plugs programmed
- No isochronous data flowing yet

Isochronous connection in use

- **Controller issues "receive" command to listener**
 - NOTE: AV/C monitors may not require a command
- **Controller issues "transmit" command to talker (e.g., AV/C DIRECT SELECT command to a tuner)**
- **Isochronous data flow commences**

Control and status registers

- Most CSRs are not applicable to wireless
- Wireless 1394 devices implement these CSRs
 - RESET_START
 - MESSAGE_REQUEST and MESSAGE_RESPONSE
 - CYCLE_TIME and BUS_TIME
- New CSRs specified by IEEE P1394.1 and wireless PAL
 - QUARANTINE and NET_UPDATE_START
- Bridge portals implement additional CSRs specified by IEEE P1394.1

Configuration ROM

- Supports all features specified by IEEE 1212 and IEEE 1394
- “Wireless 1394” differentiated by special entries in configuration ROM
 - ASCII bus identifier in bus information block
 - Bus-dependent information directory

Bus information block

30 ₁₆ ("0")	30 ₁₆ ("0")	30 ₁₆ ("0")	30 ₁₆ ("0")
capabilities	cycle_clk_acc	max_rec	mxr generation b
node_vendor_ID			chip_ID_hi
chip_ID_lo			

- ASCII bus identifier is "0000"
- Consult bus-dependent information directory for more detail

Bus information block *capabilities*

- Isochronous resource manager, bus manager and power manager have no analogs in “wireless 1394”
 - *irmc*, *bmc* and *pmc* bits are zero
- IEEE P1394.1 cycle master adjustment methods don’t work for wireless
 - *adjustable* bit is zero
- Cycle master capability is optional
 - *cmc* bit may be zero

Bus-dependent information directory

length (4)	CRC
12_{16}	specifier_ID (00 A02D ₁₆)
13_{16}	version (201 ₁₆)
21_{16}	revision (0)
31_{16}	wireless_plugs

- Specifier_ID, Version and Revision entries identify the 1394 TA document that specifies the wireless PAL
- Wireless_Plugs describes the input and output wireless plugs implemented by the device

Status

- **1394 Trade Association Specification**
 - TS2003010 (May 7, 2004)
 - Protocol Adaptation Layer (PAL) for IEEE 1394 over IEEE 802.15.3
- **Available for purchase**
