Re:	Call for Comments on Draft 80.216m Evaluation Methodology Document (IEEE 802.16m-07/014r1)	
Abstract	<p>Proposes to allocate a dedicated control channel and rate-based bandwidth to RSs for the purpose of transporting control messages from the RS to the MR-BS and BRs originated from MSs. By periodically allocating uplink bandwidth to an RS, the RS can transmit control messages necessary for the management of an MR network to the MR-BS without having to request bandwidth whenever there is a control message to transmit. Rate-based bandwidth request minimizes the overhead and relay latency involved in relaying BRs from MSs.</p>	
Purpose	Improvement in the IEEE 802.16m evaluation methodology document	
Notice	<p>This document has been prepared to assist IEEE 802.16. It is offered as a basis for discussion and is not binding on the contributing individual(s) or organization(s). The material in this document is subject to change in form and content after further study. The contributor(s) reserve(s) the right to add, amend or withdraw material contained herein.</p>	
Release	<p>The contributor grants a free, irrevocable license to the IEEE to incorporate material contained in this contribution, and any modifications thereof, in the creation of an IEEE Standards publication; to copyright in the IEEE's name any IEEE Standards publication even though it may include portions of this contribution; and at the IEEE's sole discretion to permit others to reproduce in whole or in part the resulting IEEE Standards publication. The contributor also acknowledges and accepts that this contribution may be made public by IEEE 802.16.</p>	
Patent Policy and Procedures	<p>The contributor is familiar with the IEEE 802.16 Patent Policy and Procedures <http://ieee802.org/16/ipr/patents/policy.html>, including the statement "IEEE standards may include the known use of patent(s), including patent applications, provided the IEEE receives assurance from the patent holder or applicant with respect to patents essential for compliance with both mandatory and optional portions of the standard." Early disclosure to the Working Group of patent information that might be relevant to the standard is essential to reduce the possibility for delays in the development process and increase the likelihood that the draft publication will be approved for publication. Please notify the Chair <mailto:chair@wirelessman.org> as early as possible, in written or electronic form, if patented technology (or technology under patent application) might be incorporated into a draft standard being developed within the IEEE 802.16 Working Group. The Chair will disclose this notification via the IEEE 802.16 web site <http://ieee802.org/16/ipr/patents/notices>.</p>	

Deriving a Packet Error Rate from Block Error Rates

Seung Joon Lee, Dong-Seung Kwon
ETRI, Korea

The equation (16) together with the relevant texts in Section 5.3 of the original draft does not seem to be correct. Let a burst (let it be called 'packet') be comprised of several coded FEC blocks. Then, if conditioned on the block error rates (BLERs) for the coded FEC blocks (they will be predicted by one of the PHY abstraction methods), then the block error events are independent since additive noises for the different blocks are independent. Therefore, the original text should be updated. One example for update is suggested as follows:

Text Proposal

3 5.3. Effect of Different Block Sizes Deriving a Packet Error Rate from Block Error Rates

4 [A packet is comprised of several blocks. The packet error rate (PER) is the probability that an error occurs in at least one of blocks comprising the packet. The PHY abstraction predicts the link performance, in terms of PER BLER, for a coded FEC

5 block. Often it is required to predict the PER of a burst of data comprising several code
6 blocks. Here we need to extrapolate the overall PER of the burst as a function of the
7 predicted PER BLERs across the code blocks. We note that if the channel is varying slowly,
8 packet errors across code blocks will be correlated for the blocks that are contiguously
9 allocated along time. However, due to sub-carrier permutation, packet errors across
10 code blocks allocated along the frequency axis will appear independent. The overall
11 PER of the code blocks that are correlated may be computed as the maximum of the
12 individual PER. Whereas, the PER for code blocks that are independent, may be
13 computed via the independence assumption. Therefore the overall predicted PER
14 across the burst shall be modeled as

$$15 \quad P_{burst} = 1 - \left(\prod_{i \text{ independent blocks}} (1 - PER_{i,j}) \right) \quad (16)$$

16 The exact procedure for determining the number of correlated blocks in a burst is
17 dependent on the Doppler and delay spread of the channel, and the exact specification
18 is FFS.] If a packet is comprised of J blocks and the predicted BLERs are given by $BLER_1, BLER_2, \dots, BLER_J$, then the PER is derived as

$$PER = 1 - \prod_{j=1}^J (1 - BLER_j).$$
