Comment Status D Comment Type TR

Subclause 155.2.4.11 'Hamming SD-FEC encoder' says that 'The 128-bit code words are sent as 8-bit symbols to the 400GBASE-ZR PMA sublayer on the

PMA:IS UNITDATA 0.request to PMA:IS UNITDATA 7.request inter-sublaver signals.'. Further, subclause 155.2.5.1 'Hamming SD-FEC decoder' says 'The incoming DP-16QAM symbols are digitized to an m-bit resolution by the PMA sublayer receive direction (see 155.3.3.5) and provided to the PCS receive direction by PMAIS UNITDATA 0 indication to PMA:IS UNITDATA m-1 indication inter-sublaver signals.' and that 'The Hamming SD-FEC decoder is a soft decision decoder and so requires a higher resolution than 2 bits / 4 levels for each of the signals XI. XQ. YI. and YQ.'. Finally. Figure 155-10 '400GBASE-ZR PMA functional block diagram' says 'm is implementation dependent and is the number of bits of resolution of the DP-16QAM symbols.'

Rather than operating as n parallel asynchronous PCS lanes that carry alignment markers and lane numbers that enable the original data to be restored or n lanes to be multiplex into m lanes, it appears the 400GBASE-ZR PMA service interface between the PCS and the PMA operates as an n-bit synchronous data path. transferring a single DP-16QAM symbol during each operation. This seems to be confirmed by subclause 155.2.4.3 'GMP mapper' that savs '... 400GBASE-ZR frames are not mapped to 16 PCS lanes ...'. In the case of the transmit path, the DP-16QAM symbols are encoded as 8-bit words, 2 bits representing the 4 levels for each of the in-phase and guadrature components of the X and Y polarizations. In the case of the receive path, the DP-16QAM symbols are encoded as p bits representing a levels, where p and a are implementation dependent.

This all seems to preclude the physical instantiation of the 400GBASE-ZR PMA service interface between the PCS and the PMA as a 400GAUI. This is because [1] the PMA service interface doesn't support alignment markers and lane numbers allowing multiplexing and de-multiplexing to different widths; [2] the PMA service interface width on the receive path is implementation dependant; and [3] the PMA service interface operates as a synchronous data path, transferring a single DP-16QAM symbol during each operation, requiring a skew between the bits of less than one 400GBASE-ZR frame DP-16QAM symbol time (~17.3 ps) which I don't believe a 400GAUI would meeting. This seems to be confirmed by the one example given in annexe 120A.6 'Partitioning example supporting 400GBASE-ZR' which only shows a 400GAUI 'above' the 400GBASE-ZR PCS. and not 'below'.

Based on the above add footnotes to the 'O's in the 400GAUI columns of the 400GBASE-ZR row in Table 116-5 to note the 400GAUI is only supported 'above' the 400GBASE-ZR PCS.

#### SuggestedRemedy

Add a footnote to the 'O's in the 400GAUI columns of the 400GBASE-ZR row in Table 116-5 that reads '400GAUI only supported as a physical instantiation of the 400GMII Extender (see 118.1.3).'.

Proposed Response Response Status W PROPOSED ACCEPT IN PRINCIPLE.

C/ 116	SC 116.2.3	P 28	L 53	# 5
Brown, Mat	tt	Huawei		
Comment 7	ype ER	Comment Status D		

The 400GBASE-ZR is part of the family of physical layer devices called 400GBASE-Z as defined in 1.4.144b, not 400GBASE-R. The editorial changes in 116.2.3 are therefore incorrect.

#### SuggestedRemedy

Rather than changing the first paragraph, add the following new paragraph at the end of 116.2.3: "The term 400GBASE-Z refers to a specific family of Physical Layer devices using 400GBASE-R encoding, a combination of phase and amplitude modulation, and coherent detection. The 400GBASE-ZR PCS defined in Clause 155 performs encoding of data from the 400GMII, applies FEC, and transfers the encoded data to the PMA."

This says "The term 400GBASE-R refers to a specific family of Physical Layer implementations based upon the 64B/66B coding method specified in Clause 119 or Clause 155 and the PMA specifications defined in Clause 120 or Clause 155." But these are two distinctly different "families".	P802.3cw is introducing a second PMA for 400GBASE-R. While the text "all 400GBASE-F PMAs other than 400GBASE-ZR are specified in clause 120" is correct, it also implies tha there are many 400GBASE-R PMAs besides the one in clause 155, which is not the case.
gestedRemedy	SuggestedRemedy
Revert this text and add a separate paragraph introducing 400GBASE-W	Change the first sentence to read "The 200GBASE-R PMA and 400GBASE-R PMA for PHYs other than 400GBASE-ZR are specified in Clause 120."

PROPOSED ACCEPT IN PRINCIPLE.

Replace the text at 155.2.4.1 with:

"The transmit PCS generates 66-bit blocks based upon the TXD<63:0> and TXC<7:0> signals received from the 400GMII, as specified in the transmit state diagram shown in Figure 119-14. One 400GMII data transfer is encoded into one 66-bit block. The contents of each block are contained in a vector tx coded<65:0>, which is passed to the 64B/66B to 256B/257B transcoder. tx coded<1:0> contains the sync header and the remainder of the bits contain the block payload. The rate matching described in 119.2.4.1 is not required for the 400GBASE-ZR PCS because the mapping of the transcoded block stream into the 400GBASE-ZR frame structure performs clock compensation between the two clock domains."

#### SuggestedRemedy

Add a new paragraph to subclause 155.4.7 to specify the mapping of the CRC32 and MBAS bits from block 7.11 and add a suitable footnote to figure 155-6.

#### Proposed Response Response Status W

PROPOSED ACCEPT IN PRINCIPLE.

### Add a new paragraph to subclause 155.4.7"

"The block labeled 7.11 in Figure 155-5 includes an added 72 bits containing the CRC32, the MBAS bits and a 34-bit pad. Only the information bits of 7.11 are a part of the 244 664 information bits of each input block in Figure 155-6. The CRC32 and MBAS are transmitted after the 16 384 parity bits of the prior input block Bi-1. The pad bits are not transmitted."

Comment	Type <b>TR</b>	Comment Status X		PMA block diagram
There thing in	are no characteri n the text is 155.3	to be a functional block diag stics for the DAC blocks defin .3.4 which are called the 160 2.3 PHX clauses leave out s	ned in the spec QAM encode a	ification. The closest nd signal drivers.

However, most other 802.3 PHY clauses leave out signal drivers, DACs and the like, and there are no specific requirements in 155.3.3.4, so deleting the blocks seems the right approach to making a functional block diagram.

### SuggestedRemedy

Preferably, delete the "DAC" blocks from Figure 155-10 (going straight to the output is fine) Alternatively, Relabel "16QAM Encoder and Signal Driver" (probably drawing as 2 blocks since you show I&Q paths)

Proposed Response Response Status O

Comment Typ	e TR	Comment Status D		PMA service interface

Subclause 155.2.4.11 'Hamming SD-FEC encoder' says that 'The 128-bit code words are sent as 8-bit symbols to the 400GBASE-ZR PMA sublayer on the

PMA:IS\_UNITDATA\_0.request to PMA:IS\_UNITDATA\_7.request inter-sublayer signals.'. Further, subclause 155.2.5.1 'Hamming SD-FEC decoder' says 'The incoming DP-16QAM symbols are digitized to an m-bit resolution by the PMA sublayer receive direction (see 155.3.3.5) and provided to the PCS receive direction by PMA:IS\_UNITDATA\_0.indication to PMA:IS\_UNITDATA\_m-1.indication inter-sublayer signals.' and that 'The Hamming SD-FEC decoder is a soft decision decoder and so requires a higher resolution than 2 bits / 4 levels for each of the signals XI, XQ, YI, and YQ.'. Finally, Figure 155-10 '400GBASE-ZR PMA functional block diagram' says 'm is implementation dependent and is the number of bits of resolution of the DP-16QAM symbols.'

Rather than operating as n parallel asynchronous PCS lanes that carry alignment markers and lane numbers that enable the original data to be restored or n lanes to be multiplex into m lanes, it appears the 400GBASE-ZR PMA service interface between the PCS and the PMA operates as an n-bit synchronous data path, transferring a single DP-16QAM symbol during each operation. This seems to be confirmed by subclause 155.2.4.3 'GMP mapper' that says '... 400GBASE-ZR frames are not mapped to 16 PCS lanes ...'. In the case of the transmit path, the DP-16QAM symbols are encoded as 8-bit words, 2 bits representing the 4 levels for each of the in-phase and quadrature components of the X and Y polarizations. In the case of the receive path, the DP-16QAM symbols are encoded as p bits representing q levels, where p and q are implementation dependant.

It, therefore, doesn't seem correct to define the 400GBASE-ZR PMA service interface through reference to the lane-based PMA service interface definition in 116.3 when it doesn't support the features of a lane-based service interface. Based on this, suggest that the 400GBASE-ZR PMA service interface be defined using a single .request and .indicate primitive, with a tx\_symbol and rx\_symbol parameter respectively, to reflect the synchronous data path nature of the interface.

### SuggestedRemedy

Specify the 400GBASE-ZR PMA as a single .request and .indicate primitive, with a tx\_symbol and rx\_symbol parameter respectively as follows:

- Change the three instances of 'PMA:IS\_UNITDATA\_i.request' to read 'PMA\_UNITDATA.request' in subclause 155.2.1 'Functions within the PCS'.

- Change subclause 155.1.4.2 'Physical Medium Attachment (PMA) service interface' to read as follows:

The 400GBASE-ZR PMA service interface provided by the 400GBASE-ZR PMA for the 400GBASE-ZR PCS is described in an abstract manner and does not imply any particular implementation. The 400GBASE-ZR PMA Service Interface supports the exchange of

SORT ORDER: Clause, Subclause, page, line

encoded DP-16QAM symbols between the PCS and PMA sublayer. The 400GBASE-ZR PMA service interface is defined in 155.3.2.

- Change the last paragraph of subclause 155.2.4.11 'Hamming SD-FEC encoder' to read:

The 128-bit code words are sent as 8-bit encoded DP-16QAM symbols to the 400GBASE-ZR PMA sublayer using sixteen PMA\_UNITDATA.request messages.

- Change the text '... by PMA:IS\_UNITDATA\_0.indication to PMA:IS\_UNITDATA\_m-1.indication inter-sublayer signals.' to read '... by the PMA\_UNITDATA.indication primitive.' in subclause 155.2.5.1 'Hamming SD-FEC decoder'.

- Change subclause 155.3.2 '400GBASE-ZR PMA service interface', adding new subclauses 155.3.2.1 through 155.3.2.2.3, to read:

### 155.3.2 400GBASE-ZR PMA service interface

The 400GBASE-ZR PMA Service Interface supports the exchange of encoded DP-16QAM symbols between the PCS and PMA sublayer. The inter-sublayer 400GBASE-ZR PMA service interface is described in an abstract manner and does not imply any particular implementation. The inter-sublayer service interface primitives are defined as follows:

PMA\_UNITDATA.request PMA\_UNITDATA.indication PMA\_SIGNAL.indication

The PMA\_UNITDATA.request primitive is used to define the transfer of a DP-16QAM symbol from the 400GBASE-ZR PCS to the 400GBASE-ZR PMA. The PMA\_UNITDATA.indication primitive is used to define the transfer of a DP-16QAM symbol from the 400GBASE-ZR PMA to the 400GBASE-ZR PCS. The PMA\_SIGNAL.indication primitive is used to define the transfer of signal status from the 400GBASE-ZR PMA to the 400GBASE-ZR PCS.

155.3.2.1 PMA\_UNITDATA.request

This primitive defines the transfer of encoded DP-16QAM symbols in the tx\_symbol parameter from the 400GBASE-ZR PCS to the 400GBASE-ZR PMA.

155.3.2.1.1 Semantics of the primitive

PMA\_UNITDATA.request (tx\_symbol)

During transmission, the PMA\_UNITDATA.request simultaneously conveys 8 bits of a 128bit code word generated by the SD-FEC encoder (see 155.2.4.11) representing an encoded DP-16QAM symbol to the PMA. The encoding used for the in-phase and guadrature-phase components of the X and Y polarization is defined in subclause 155.3.3.1.

155.3.2.1.2 When generated

The PCS generates sixteen PMA\_UNITDATA.request messages for each 128-bit code word from the PCS SD-FEC encoder. The messages convey the least significant octet C<7:0> first, most significant octet C<127:120> last, with code word bits C<n+7:n> mapped to tx\_symbol<7:0>. The nominal rate of PMA\_UNITDATA.indication messages is 57.78 GBd.

155.3.2.1.3 Effect of receipt

The PMA continuously forms the tx\_symbol parameters received in sixteen consecutive PMA\_UNITDATA.indication messages into 128-bit code words that are passed to the PMA Gray mapping and polarization distribution function (see 155.3.3.1).

155.3.2.2 PMA UNITDATA.indication

This primitive defines the transfer of encoded DP-16QAM symbols in the rx\_symbol parameter from the 400GBASE-ZR PMA to the 400GBASE-ZR PCS.

155.3.2.2.1 Semantics of the primitive

PMA\_UNITDATA.indication (rx\_symbol)

During reception, the PMA\_UNITDATA.indication simultaneously conveys m bits of an nbit code word generated by the symbol de-interleaving function (see 155.3.3.8) representing an encoded DP-16QAM symbol to the 400GBASE-ZR PCS where m is implementation dependent, representing the number of bits of the encoded DP-16QAM symbol, and n = 16 x m.

155.3.2.2.2 When generated

The PMA generates sixteen PMA\_UNITDATA.indication messages for each n-bit code word generated by the PMA symbol de-interleaving function. The messages convey the least significant m bits of the n-bit code word first. The nominal rate of PMA\_UNITDATA.indication messages is 57.78 GBd.

155.3.2.2.3 Effect of receipt

The PCS continuously forms the rx\_symbol parameters received in sixteen consecutive PMA\_UNITDATA.indication messages into n-bit code words that are passed to the PCS Hamming SD-FEC decoder function (see 155.2.5.1).

155.3.2.3 PMA SIGNAL indication

This primitive defines the transfer of the status of the PMA receive process in the SIGNAL\_OK parameter from 400GBASE-ZR PMA to the 400GBASE-ZR PCS.

SORT ORDER: Clause, Subclause, page, line	

C/ 155 SC 155.3.2 Page 58 of 122 9/9/2022 3:06:11 PM

### 155.3.2.3.2 When generated

The PMA generates a PMA\_SIGNAL.indication message whenever there is change in the value of the SIGNAL\_OK parameter (see 155.3.3.9).

155.3.2.2.3 Effect of receipt

The PCS Synchronization process monitors the PMA\_SIGNAL.indication primitive for a change in the SIGNAL\_OK parameter (see 155.2.1).

- Move the last paragraph of the current subclause to a new subclause 155.3.3.9 titled 'Signal Indication Logic (SIL)'.

- Change the last paragraph of subclause 155.3.3.8 'Polarization combining and symbol deinterleaving' to read:

The sixteen encoded DP-16QAM symbols are transferred to the 400GBASE-ZR PCS sublayer as m-bit DP-16QAM symbols using sixteen PMA\_UNITDATA.indication messages.

- Change 'PMA:IS\_UNITDATA\_0.request to PMA:IS\_UNITDATA\_7.request' to read 'PMA\_UNITDATA.request' and 'PMA:IS\_UNITDATA\_0.indication to PMA:IS\_UNITDATA\_m-1.indication' to read ' PMA\_UNITDATA.indication' in Figure 155-2 'Functional block diagram'.

- Change 'PMA:IS\_UNITDATA\_0.request to PMA:IS\_UNITDATA\_7.request' to read 'PMA\_UNITDATA.request' and 'PMA:IS\_UNITDATA\_0.indication to PMA:IS\_UNITDATA\_m-1.indication' to read ' PMA\_UNITDATA.indication' in Figure 155-10 '400GBASE-ZR PMA functional block diagram'.

aw, David       Hewlett Packard Enterprise         Comment Type       TR       Comment Status       X       PS generator         There is no specification of how the PRBS10 sequence is mapped to 16QAM symbols.       From review of Table 155-6 it appears that the generator in Figure 155-13 is used to produce 232 bits. The even bits are mapped to the in-phase component of the 16QAM symbol, odd bits mapped to the quadrature-phase component of the 16QAM symbol, with a 0 mapped to a '-3' and a 1 mapped to a '3'.         SuggestedRemedy         Suggest that the second paragraph of subclause 155.3.3.3.3 be changed to read:         The seed is reset at the start of every sub-frame, so that the same 116 symbols, [P0,,P115] are inserted into every sub-frame of the same polarization. For each polarization X and Y, the generator produces 232 bits PRBS[231:0] that are mapped to 116 16QAM symbols, symbols,         [P0,,P115]	Law, David       Hewlett Packard Enterprise         Comment Type       T       Comment Status       X       PS gene         Subclause 155.3.3.3.3 'Pilot sequence (PS)' says that 'The seed is reset at the start of every sub-frame'. Isn't it the generator that is reset at the start of every sub-frame using the seed value?       SuggestedRemedy         Suggest that the text 'The seed is reset at the start of every sub-frame, so that the same'. be changed to read 'The generator is initialized using the seed at the start of every sub-frame, so that the same'.         Proposed Response       Response Status       O         C/ 155       SC 155.3.3.3.3       P 57       L 10       # 274         Law, David       Hewlett Packard Enterprise
There is no specification of how the PRBS10 sequence is mapped to 16QAM symbols. From review of Table 155-6 it appears that the generator in Figure 155-13 is used to produce 232 bits. The even bits are mapped to the in-phase component of the 16QAM symbol, odd bits mapped to the quadrature-phase component of the 16QAM symbol, with a 0 mapped to a '-3' and a 1 mapped to a '3'. SuggestedRemedy Suggest that the second paragraph of subclause 155.3.3.3.3 be changed to read: The seed is reset at the start of every sub-frame, so that the same 116 symbols, [P0, ,P115] are inserted into every sub-frame of the same polarization. For each polarization X and Y, the generator produces 232 bits PRBS[231:0] that are mapped to 116 16QAM symbols,	Subclause 155.3.3.3.3 'Pilot sequence (PS)' says that 'The seed is reset at the start of every sub-frame'. Isn't it the generator that is reset at the start of every sub-frame using the seed value?         SuggestedRemedy         Suggest that the text 'The seed is reset at the start of every sub-frame, so that the same' be changed to read 'The generator is initialized using the seed at the start of every sub-frame, so that the same'         Proposed Response       Response Status       0         Cl 155       SC 155.3.3.3.3       P 57       L 10       # 274
From review of Table 155-6 it appears that the generator in Figure 155-13 is used to produce 232 bits. The even bits are mapped to the in-phase component of the 16QAM symbol, odd bits mapped to the quadrature-phase component of the 16QAM symbol, with a 0 mapped to a '-3' and a 1 mapped to a '3'.  SuggestedRemedy Suggest that the second paragraph of subclause 155.3.3.3.3 be changed to read: The seed is reset at the start of every sub-frame, so that the same 116 symbols, [P0,,P115] are inserted into every sub-frame of the same polarization. For each polarization X and Y, the generator produces 232 bits PRBS[231:0] that are mapped to 116 16QAM symbols,	every sub-frame'. Isn't it the generator that is reset at the start of every sub-frame using the seed value?         SuggestedRemedy         Suggest that the text 'The seed is reset at the start of every sub-frame, so that the same' be changed to read 'The generator is initialized using the seed at the start of every sub-frame, so that the same'.         Proposed Response       Response Status       0         Cl       155       SC 155.3.3.3.3       P 57       L 10       # 274
a 0 mapped to a '-3' and a 1 mapped to a '3'. SuggestedRemedy Suggest that the second paragraph of subclause 155.3.3.3.3 be changed to read: The seed is reset at the start of every sub-frame, so that the same 116 symbols, [P0, ,P115] are inserted into every sub-frame of the same polarization. For each polarization X and Y, the generator produces 232 bits PRBS[231:0] that are mapped to 116 16QAM symbols,	Suggest that the text 'The seed is reset at the start of every sub-frame, so that the same' be changed to read 'The generator is initialized using the seed at the start of every sufframe, so that the same'. Zimmerman	, George	CME	Consulting/APL Gro	oup, Cisco, Commscope, Ma	
Comment Ty	pe TR	Comment Status	Х	PMA description	

"The signals are sampled by an ADC on each lane at a sampling rate." "The details of the ADC . are implementation specific". This is a description of an implementation, not appropriate for an interoperability specification. If someone could do the signal processing optically, analog, or by magic, it would still comply with the standard. The fact that an ADC is used, isn't a part of the interoperability standard, or even any of the characteristics of the ADC. Hence the mention is inappropriate and should be deleted. The sentence works just fine anyways and describes the processing without the "by an ADC".

### SuggestedRemedy

Change header of 155.3.5 to Receive signal sampling. On line 50, Delete "by an ADC" Change line 54 to "The details of the sampling, including any quantization and the chosen sampling rate are implementation specific." Replace "ADC" with "Sampler" in figure 155-10.

Proposed Response Response Status O

PMA lanes

C/ 155	SC 155.4.2.1	P 60	L 34	# 140
Nicholl, Ga	ary	Cisco System	IS	

Comment Type T Comment Status D

Definiton of "pma\_alignment \_valid" variable. Reading the previous text it is not clear exactly what consititues a PMA lane, and how many PMA lanes there are, and how each PMA lane is assigned a unique lane number ? The definition also refers to "PMA lanes are deskewed". I don't see any mention of PMA lane deskew in the functional block diagram in Figure 155-10.

### SuggestedRemedy

Maybe this is all clearly defined earlier in the document. If so then the editors can reject this comment with a reference to the appropriate section of text. If not then the variable description needs to be updated to better refelct thefunctional descriptions earlier in this clause. This comment also applies to other variables defined in 155.4.2.1, that refer to "PMA lanes".

Comment Type	т	Comment Status	D		state variables

The description of the 'reset' variable says that it is 'A boolean variable that controls the resetting of the PCS and PMA sublayers' and that 'It is true whenever a reset is necessary including when reset is initiated from the MDIO ... and when the MDIO has put the PCS and PMA sublayers into low-power mode.'.

The PMA and PCS are separate MMDs (see Table 45-1). The PMA/PMD reset bit is 1.0.15 and the low power bit is 1.0.11, both found in PMA/PMD control 1 register. The PCS reset bit is 3.0.15 and the low power bit is 3.0.11, both found in the PCS control 1 register. Since these registers are in separate MMDs, and since their state is not communicate across the PMA service interface, the PMA and PCS resets can operate independently.

#### SuggestedRemedy

[1] Rename the 'reset' variable used in Figure 155-14 'Frame alignment word (FAW) lock state diagram' to be 'pma\_reset'.

[2] Rename the 'reset' variable used in Figure 155-15 'PMA deskew state diagram' to be 'pma\_reset'.

[3] Rename the 'reset' variable used in Figure 155-16 'Alignment marker lock state diagram' to be 'pcs\_reset'.

[4] Rename the 'reset' variable defined in subclause 155.4.2.1 'Variables' to be 'pma\_reset' and change the description to read 'A Boolean variable that controls the resetting of the PMA sublayer. It is true whenever a reset is necessary including when reset is initiated from the MDIO, during power on, and when the MDIO has put the PMA sublayer into low-power mode.

[5] Add a definition of the 'pcs\_reset' variable to subclause 155.4.2.1 'Variables' with the description 'A Boolean variable that controls the resetting of the PCS sublayer. It is true whenever a reset is necessary including when reset is initiated from the MDIO, during power on, and when the MDIO has put the PCS sublayer into low-power mode.

The description of the variable 'current pmal' says 'The PMA lane number is determined

Hewlett Packard Enterprise

by the FAW payloads based on the mapping defined in 155.3.3.3.1.' and the description of the variable 'pma\_lane' says 'The PMA lane number is determined by matching the received 22-symbol sequence to the values in one of the columns of Table 155-3 ...'. Subclause 155.3.3.3.1, nor Table 155-3, provide any lane numbers.

The PMA lane number is not referenced outside the state diagrams, other than in Table 155-9 where pma\_lane\_mapping<x> is mapped to register 3.400 through 3.403, which doesn't seem correct as these are PCS lane registers, not PMA lane registers (see my other comment on this). As a result, rather than add PMA lane numbers to subclause 155.3.3.1 and/or Table 155-3, suggest references to 'PMA lane numbers' be changed to 'PMA lane identifiers' with the values 'lx', 'Qx', 'ly' and 'Qy'. The state diagram can compare PMA lane identifiers to see if they match and can test for a unique PMA lane identifier for each PMA lane as easily as it can for PMA lane numbers.

In addition, the description of the 'faw\_valid' variable says 'The sequence is considered to be valid if at least 36 bits match the 44 known bits of the FAW pattern described in 155.3.3.3.1.'. The description of the variable 'current\_pmal' however says 'The PMA lane number is determined by the FAW payloads based on the mapping defined in 155.3.3.3.1.'. Similarly, the description of the variable 'pma\_lane' says 'The PMA lane number is determined by matching the received 22-symbol sequence to the values in one of the columns of Table 155-3 ...'. Neither mention the '36 out 44' approach used for the 'faw\_valid' variable.

The 'current\_pmal' description could imply a requirement for a full match to a column of Table 155-3, and the 'pma\_lane' description requires a full match to a column of Table 155-3. Since the entry into states where 'current\_pmal' is used is based on faw\_valid = TRUE, doesn't this mean that the use of the '36 out 44' approach, which permits 8 16QAM symbols to not match, needs to be considered when determining 'current\_pmal' and 'pma\_lane'. As a worst-case example, couldn't a faw\_valid = TRUE result from eight 16QAM symbols not matching due to errors on just one phase of just one of polarization. This would seem to imply that the compare for the values received on a lane with the columns of Table 155-3 also needs to permit eight values not matching.

In the case of 'current\_pmal' and 'pma\_lane', as there are only 22 values in a column of Table 155-3, it would seem a match would have to be valid if at least 14 values received on the lane match the 22 known values defined in a column to address the worst-case of all eight errors on one phase of one of polarization. It seems there may, however, be another approach to determine 'current\_pmal' and 'pma\_lane'. Doesn't the PMD lane mapping row selected from Table 155-7 to achieve faw\_valid = TRUE inherently provide the 'current\_pmal' and 'pma\_lane' values (see my comment on faw\_valid)?

Finally, as this variable is used by a state diagram within the PMA, which sits above the PMD, the text '... is recognized on a given lane of the PMA service interface.' should read '... is recognized on a given lane of the PMD service interface.'.

SuggestedRemedy

[1] Change the description of the first\_pmal variable to read as follows (note my other comment to change the coherent signal labels in Table 155-7 would impact this item if accepted):

A variable that holds the PMA lane identifier corresponding to the first FAW sequence that is recognized on a given lane of the PMD service interface. It is compared to the PMA lane identifier corresponding to the next FAW payload that is tested. The PMA lane identifier is the value for the given lane in the row of Table 155-7 that defines the PMD service interface lane mapping used to find the match for the current FAW sequence as described in the faw\_valid variable.

#### Values:

Ix: Value for given lane from mapping used in Table 155-7 to find the current FAW sequence is XI.

Qx: Value for given lane from mapping used in Table 155-7 to find the current FAW sequence is XQ.

ly: Value for given lane from mapping used in Table 155-7 to find the current FAW sequence is YI.

Qy: Value for given lane from mapping used in Table 155-7 to find the current FAW sequence is YQ.

[2] Change the description of the current\_pmal variable to read as follows:

A variable that holds the PMA lane identifier corresponding to the current FAW sequence that is recognized on a given lane of the PMD service interface. It is compared to the variable first\_pmal to confirm that the location of the FAW sequence has been detected. The PMA lane identifier is the value for the given lane in the row of Table 155-7 that defines the PMD service interface lane mapping used to find the match for the current FAW sequence as described in the faw valid variable.

## Values:

See first\_pmal.

[3] Change the description of the pma\_lane variable to read as follows:

pma\_lane

A variable that holds the PMA lane identifier received on lane x of the PMA service interface when faws\_lock<x> = TRUE. The PMA lane identifier is determined by matching the received 22-symbol FAW sequence to the values in one of the columns of Table 155-3. The PMA lane identifier is the value for the given lane in the row of Table 155-7 that defines the PMD service interface lane mapping used to find the match for the current FAW sequence as described in the faw\_valid variable.

The description of the 'FAW COMPARE' function in subclause 155.4.2.2 'Functions' savs that 'If current pmal and first pmal both found a match and ... faw match is set to true.'. Since faw valid '... is considered to be valid if at least 36 bits match the 44 known bits of the FAW pattern ...'. I assume rather than a 'match', this really should say something along the lines of 'if at least 36 symbols of the current receive 22-symbol block match the 44 known bits of the FAW pattern'.

It however seems simpler to just add faw valid is TRUE as a condition to enter the COMP state, which would become 'faw counter done \* faw valid', and have a path from the 'COUNT 2' state to the 'INVALID FAW' state if 'faw counter done \* !faw valid' is FALSE. This would also mirror the similar use of the 'FAW COMPARE' function in the 'COMP 2ND' state where the condition to transition to the state is 'faw counter done \* faw valid' and 'faw counter done \* !faw valid' results in a transition to the 'FAW SLIP' state.

### SuggestedRemedy

[1] Change the text 'If current pmal and first pmal both found a match and indicate the same PMA lane number, faw match is set to true' in the description of the FAW COMPARE function to read 'If current pmal and first pmal indicate the same PMA lane number. faw match is set to true'.

[2] Change the condition on the transition from the 'COUNT 2' state to the 'COMP' state in Figure 155-14 'Frame alignment word (FAW) lock state diagram' to read 'faw counter done \* faw valid'.

[3] Add a transition from the 'COUNT 2' state to the 'INVALID FAW' state in Figure 155-14 'Frame alignment word (FAW) lock state diagram' that reads 'faw counter done \* !faw valid'.

The description of the 'restart lock' variable says 'A boolean variable that is set by the frame alignment word (FAW) lock process to reset the synchronization process on all PMA lanes. It is set to TRUE when 15 FAWs in a row fail to match (15 BAD state).'. While the restart lock variable is used in the frame alignment word (FAW) lock process described in Figure 155-14, it is also used in the Alignment marker lock process described in Figure 155-16.

### SuggestedRemedv

[1] Rename all instances of the 'restart lock' variable used in Figure 155-14 'Frame alignment word (FAW) lock state diagram' to be 'pma restart lock'.

[2] Rename all instances of the 'restart lock' variable used in Figure 155-16 'Alignment marker lock state diagram' to be 'pcs restart lock'.

[3] Rename 'restart lock' variable in subclause 155.4.2.1 'Variables' to be 'pma restart lock'.

[4] Add a definition of the 'pcs restart lock' variable to subclause 155.4.2.1 'Variables'.

Proposed Response Response Status O

Comment Type	т	Comment Status X		state diagrams

Text on FAW synchronization seems to imply that there is a FAW synchronization process for each lane, for a total of 4 independent FAW synchronization processes. Actually there are 2 FAW synchronization processes, one per polarization (see figure 115.10 and clause 155.3.3.7)

#### SuggestedRemedy

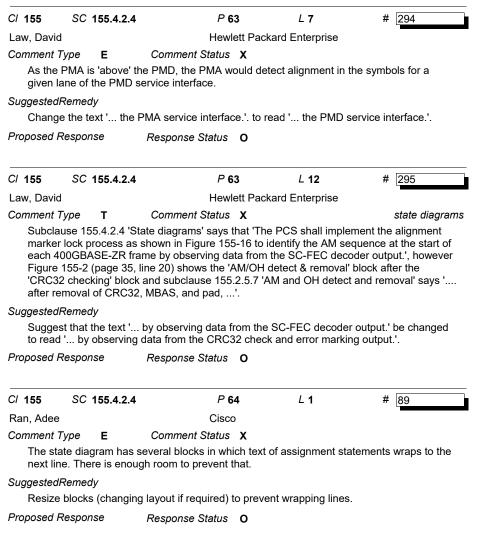

Replace: "The synchronization process operates independently on each lane" with: "The synchronization process operates independently on each polarization"

Comment Ty	vpe TR	Comment Status	х			state diagrams	

Based on the description of the 'faw\_valid' variable, and slide 4 of the contribution 'faw\_valid analysis' from Mike Sluyski

<https://www.ieee802.org/3/cw/public/22\_0523/sluyski\_3cw\_01a\_220523.pdf#page=4> referencing a 'QPSK FAW' value of 44, it seems a valid FAW sequence can only be detected across all four lanes. As a result, it will only be possible to achieve FAW lock on all lanes, or no lanes. There is no case where some lanes can be FAW locked, and others are not. There, therefore, seems no need to have four instances of the Frame alignment word lock state diagram (page 63, line 3). If there were, they wouldn't operate independently on each lane (page 63, line 5), and instead would operate in lock step.

It therefore seems that the four Frame alignment word lock state diagram can be collapsed in to one if the first\_pmal and current\_pmal variables hold the mapping number found in table 155-7 to achieve faw\_valid rather than the lane number. The PMA deskew state diagram can then be removed.

### SuggestedRemedy

[1] Delete the variables 'pma\_alignment\_valid', 'all\_locked', and PMA\_lane\_mapping<x> from subclause 155.4.2.1 'Variables' and Figure 155-14.

[2] Change the description of the 'faws\_lock<x>' variable (page 61, line 1) to read:

#### faws lock

A Boolean variable that is set to true when the receiver has detected the location of the FAW.

[3] Change the description of the faw\_valid as suggested in my comment about faw\_valid.

[4] Change the description of the first\_pmal to read (this overrides my other comment about first\_pmal):

A variable that holds the PMA lane mapping number found in the first column of Table 155-7 corresponding to the PMD service interface lane mapping used to find the match for the first FAW sequence. It is compared to the PMA lane mapping number corresponding to the next FAW payload that is found.

[5] Change the description of the current\_pmal to read (this overrides my other comment about current\_pmal):

A variable that holds the PMA lane mapping number found in the first column of Table 155-7 corresponding to the PMD service interface lane mapping used to find the match for the current FAW sequence. It is compared to the variable first\_pmal to confirm that the location of the FAW sequence has been detected.

[6] Change all instances of '... PMA lane number ...' to '... PMA lane mapping number ...'.

 MDIO mapping

Register bits 3.52.3:0 (IEEE Std 802.3-2022 subclause 45.2.3.25) are PCS lane alignment lock status registers, yet they are mapped to PMA lane alignment lock variables (faw\_lock<3:0>). Similarly, register bit 3.50.12 is the PCS alignment status, yet it is mapped to the PMA alignment status variable (pma\_align\_status).

If there was a 400GBASE-ZR framing issue on a link where the PMA framing was operating correctly, the faws\_lock<3:0> bits and the pma\_align\_status would all be true based on the respective frame alignment word (FAW) lock state diagrams, while the PCS would not be aligned based on the alignment marker lock state diagram. In that case, the current regsiter mapping would indicate that all the PCS lanes were aligned, and the overall PCS was aligned, when in fact this is not the case. This would seem to be misleading information to provide in the management registers in such a case.

Further, register 3.400 (IEEE Std 802.3-2022 subclause 45.2.3.49) through 3.419 are the 'PCS lane mapping registers, lanes 0 through 19' and these registers report the PCS lane number provide by the alignment marker for the respective PMA service interface lane. Table 155-9, however, maps these PCS lane mapping registers to the PAM lane mapping variable 'pma\_lane\_mapping<x>' output by Figure 155-14, the 'Frame alignment word (FAW) lock state diagram'.

Subclause 155.2.4.3 'GMP mapper' says 'The first 1920 bits of the frame contain alignment markers (AM).' and that 'These are identical to the 16 x 120b markers defined for 400GBASE-R in 119.2.4.4.2.'. Since the 16 different 400GBASE-R PCS lane alignment markers are all placed in a single 400GBASE-ZR alignment marker (see 155.2.4.4.1) it seems that 400GBASE-ZR frames are not mapped to 16 PCS lanes. This seems to be confirmed in subclause 155.2.4.3 'GMP mapper' which says '... 400GBASE-ZR frames are not mapped to 16 PCS lanes across the PMA service interface, therefore there is no PCS lane alignment lock status nor PCS Lane mapping.

Finally, register bits 3.52.3:0, 3.50.12, and 3.400 through 3.403, which are all PCS register bits defined for MMD 3 (see IEEE Std 802.3-2022 Table 45-1), are mapped to variables found in the PMA. As illustrated in Figure 120A-9 (page 103), MMD 3 does not have access to the PMA (or PMD) as they are in MMD 1.

Based on the above, suggest that two new subclauses are added to say that registers 3.52, 3.53 and 3.400 through 3.403 are not used by the 400GBASE-ZR PCS because the 400GBASE-ZR PCS does not use PCS lanes across the PMA service interface. Require all PCS lane alignment bits to be set to zero. The content of the PCS lane mapping registers does not need to be defined because their content is only valid when the respective PCS lane alignment bit is set to one. In addition, suggest that the PCS lane alignment status bit be mapped from the 'amps\_lock' variable generated by the Figure 155-16, the PCS alignment marker lock state diagram.

### SuggestedRemedy

TYPE: TR/technical required ER/editorial required GR/general required T/technical E/editorial G/general COMMENT STATUS: D/dispatched A/accepted R/rejected RESPONSE STATUS: O/open W/written C/closed U/unsatisfied Z/withdrawn SORT ORDER: Clause, Subclause, page, line

Suggested changes:

[1] Delete the antepenultimate row of Table 155-9.

[2] Add a new subclause 155.5.1 as follows:

155.5.1 PCS lane alignment registers

The PCS lane alignment registers (registers 3.52 and 3.53) are not used as the 400GBASE-ZR PCS does not use PCS lanes across the PMA service interface (see 155.2.4.3). A 400GBASE-ZR PCS shall return a zero for all bits in these registers.

[3] Change the variable 'pma\_align\_status' in the 'ZR-PCS/PMA variable' column of the penultimate row of Table 155-9 to 'amps\_lock'.

[4] Delete the last row of Table 155-9.

[5] Add a new subclause 155.5.2 as follows:

155.5.2 PCS lane mapping registers

The PCS lane mapping registers (registers 3.400 through 3.419) are not used as the 400GBASE-ZR PCS does not use PCS lanes across the PMA service interface.

Assuming just 4 bits ENOB from 10 MHz to 29.9 MHz the reference receiver will have	"3rd-order super Gaussian filter with RRC = 0.2"
additional penalty than real receiver that has typically 6+ bits ENOB at low frequncies and about 4 bits at high frequncy	This is an uncommon way to specify a filter, and it is unclear.
uggestedRemedy	
If there is interest I can bring a frequncy dependent ENOB mask	RRC seems to stand for is root raised cosine (0.2 may be the roll-off parameter beta), but this filter is not "super Gaussian" and it's unclear what "3rd-order" means for a raised
roposed Response Response Status W	cosine. Or is it a different filter?
PROPOSED REJECT.	Also, the cutoff frequency is not specified.
No suggested remedy provided	SuggestedRemedy Rewrite to clarify.
