# Reusing 4B3T in 100BASE-T1L PCS

- 4B3T in 10BASE-T1L achieves bounded disparity for intrinsic safety application. However, time-domain simulations ([Murray 3dg 03122024](#), [Tingting 3dg 12 03 2024](#)) show insufficient SNR margin for 500m transmission.
- Coupled noise on cable impacts on the PAM3 decision, in the case of 1kV EFT and screw terminal connectors ([Brychta 3dg update B 2024-Mar-09](#)). The impact aggregates at 2kV EFT (IEC61000-4-4).
- FEC is a simple and direct method to correct both random and burst errors. Transmit signal level keeps the same (still PAM3), allowing easier analog/digital signal processing.
  - For latency-sensitive application, FEC can be bypassed.

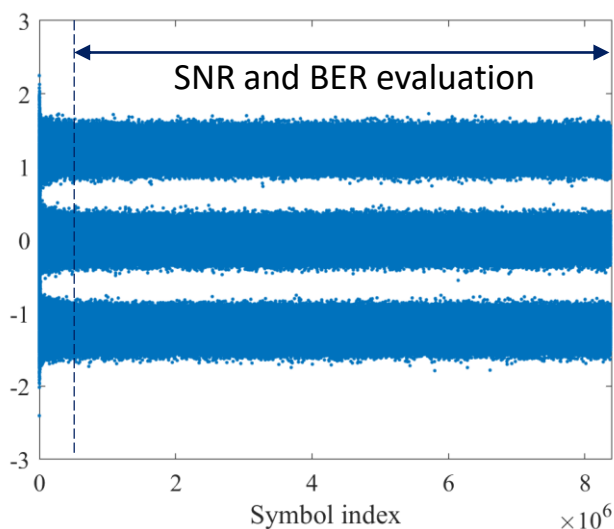

# PCS block coding and FEC option

- For 500m transmission, RS (128, 122) in GF(2<sup>8</sup>) field with 6 parity symbols provide 3.75dB net coding gain and tolerates 225ns burst, sufficient for both burst and random error correction. The signal bandwidth is slightly increased by 2.5MHz.
- When FEC is turned off, PCS function includes 64B/65B, scrambling and 4B3T mapping. The PCS latency is about 0.8us, still leaving 0.7us for PMA.
  - 16B/17B with the same coding principle as 64B/65B may be considered to further reduce PCS latency. For example, 1 bit is inserted every 15 17b blocks, symbol rate keeps the same ( $100 \times \frac{(15 \times 17 + 1)}{15 \times 16} \times \frac{3}{4} = 80 \text{Mbaud}$ ) as the case with FEC.

# Time-domain simulation for 80MBaud 4B3T PAM3

- Simulation parameters: 2.4Vpp, 12-bit DAC/ADC, -113.28dBm/Hz AWGN, 802.3dg baseline IL, 30-tap FFE and 5-tap DFE. Without FEC, the required SNR at BER of  $10^{-10}$  for PAM-3 is 20.2 dB.
- Simulation results: 80MBaud 4B3T PAM3 achieves 19.6dB SNR, and no bit error is observed for  $10^7$  bits. The 0.6dB SNR gap can be solved by RS (128, 122) with 3.75dB NCG, leaving some margin for burst errors.

# Conclusion

---

- 4B3T adopted in 10BASE-T1L to limit the running disparity can be reused in 100BASE-T1L. Apart from the advantage of compatibility, the three-level signal (PAM3) also makes PHY design easier.
- To ensure BER  $<1e-10$  after 500m transmission, FEC e.g. RS(128,122,3,8) with 3.75dB NCG and 225ns burst error correction capability can be used for 4B3T PAM3. The overall PCS overhead is ~6.7% and the signal bandwidth is only increased by 2.5MHz (from 37.5MHz to 40MHz).
- For latency-sensitive application, FEC can be bypassed. The symbol rate keeps the same, minimizing PHY cost.

**Thank you!**
